Health Benefit Design Options

FOR ALBERTA HEALTH & WELLNESS

Aon Consulting

AON

Executive Summary
29 March 2006

This document contains advice, proposals, recommendations, analyses or policy options developed for the Minister of Alberta Health and Wellness, and/or department of Alberta Health and Wellness.

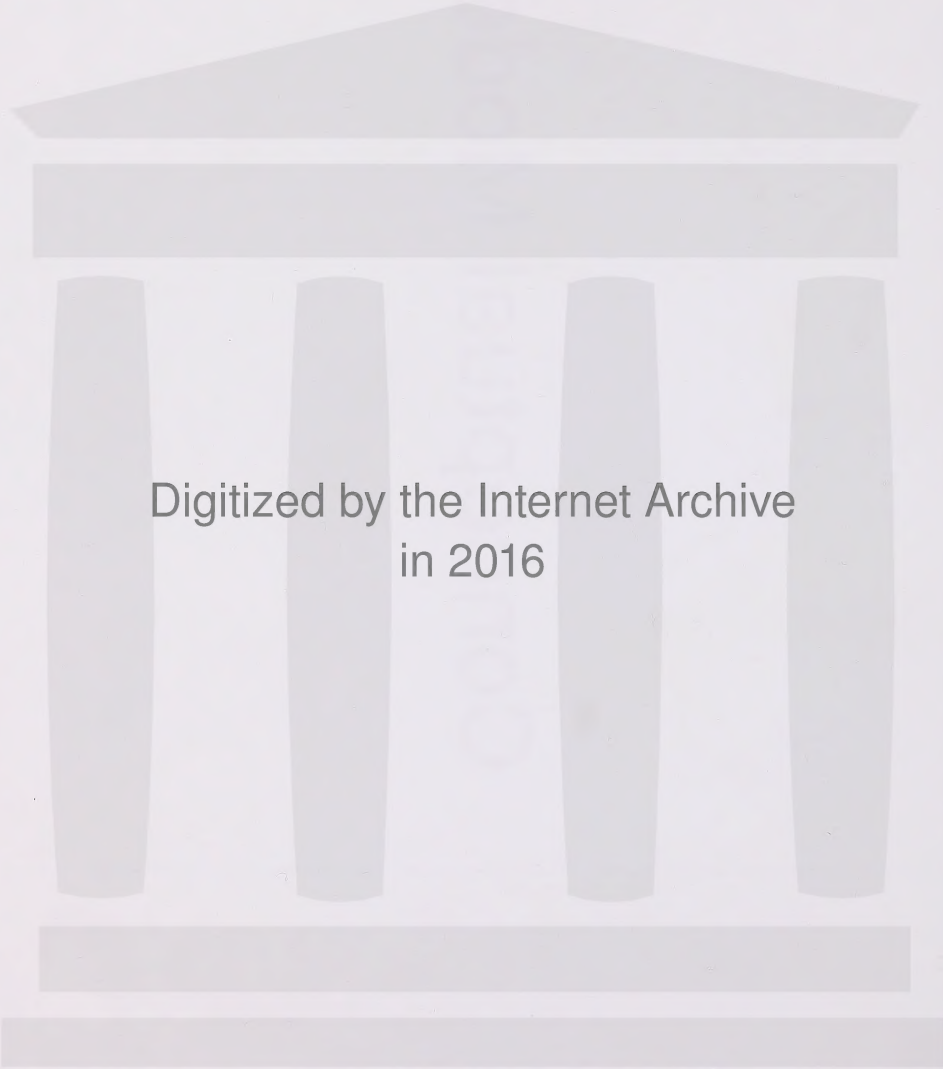

Contents

1. Project Scope
2. Conceptual Models
3. Key Concepts
4. Prescription Drugs
5. Continuing Care
6. Non-Emergency Health
7. Supplemental Health
8. Economic Model
9. Final Comments

Project Scope

- Develop health insurance models for each of the following:
 - Prescription drugs
 - Continuing care
 - Non-emergency health care
 - Supplemental health products and services
- Each group of health care services interacts differently with each conceptual model
- Evaluation criteria based on insurance plan's promotion of:
 - Personal responsibility
 - Efficiency
 - Cost control

Conceptual Models

Digitized by the Internet Archive
in 2016

Conceptual Models Reviewed

1. Mandatory Public Health Insurance
2. Mandatory Public Health Insurance with Optional Private Supplemental Coverage
3. Mandatory Public Health Insurance with Optional Private Replacement Coverage
4. Mandatory Private Health Insurance with Public Premium Pooling
5. Mandatory Private Health Insurance
6. Optional Private Health Insurance

Mandatory Public Health Insurance

- Provide health insurance through a publicly run insurance plan
- Set up plan as any private insurer would, but run by Government of Alberta
- Premiums may be income and/or cost based (i.e. a flat fee)
- Use individual risk ratings to set premiums, or a community rating of the entire population
- Where premiums have a flat fee, the government could make payments on behalf of low income earners

Mandatory Public Health Insurance

Optional Private Supplemental Coverage

- Choice in health insurance:
 - Mandatory health insurance via publicly run insurance plan
 - Optional private insurance as a supplement to public insurance
- Premiums may be income and/or cost based
- Where premiums have a flat fee, the government could make payments on behalf of low income earners
- Private plans require regulation and oversight for solvency levels
- Private plans may require:
 - Community rating; or
 - More likely, individual premiums based on health risk assessments

Mandatory Public Health Insurance

Optional Replacement Coverage

- Choice in health insurance:
 - Mandatory health insurance via publicly run insurance plan
 - Optional private insurance as a replacement (opt-out) to public insurance
- Premiums may be income and/or cost based
- Where premiums have a flat fee, the government could make payments on behalf of low income earners
- Private plans require regulation and oversight for solvency and coverage levels
- Private plans may require:
 - Community rating; or
 - More likely, individual premiums based on health risk assessments

Mandatory Private Health Insurance

Public Premium Pooling

- Universal coverage and funding through common funding pool
- Choice between private insurers may offer multiple plans that meet a minimum standard of coverage
- Insurers paid for basic coverage from common funding pool
- Additional coverage may be purchased to supplement the basic plan with a higher level of health- related services
- Private plans require regulation and oversight for solvency and coverage levels

Mandatory Private Health Insurance

- Mandatory coverage required
- Payments to insurers directly from private parties (individuals or employers)
- Where required for social policy, payments made by government on behalf of individuals
- Private insurers may not be able to provide 'reasonable' rates if liability for future claims is unlimited
- Private insurers may offer multiple plans that meet a minimum standard of coverage, increasing the level of choice
- Risk pooling may be necessary to allow insurers to provide coverage to high risk individuals
- Additional coverage may be purchased to supplement the minimum regulatory requirements with a higher level of health-related services
- Private plans require regulation and oversight for solvency and coverage levels

Optional Private Health Insurance

- Coverage is optional and may be obtained from any private insurer in the market
- Currently this is the type of coverage often provided by employers for drugs and supplemental health care
- Regulation is generally limited to solvency for this model

Key Concepts

Aging Population

- Number of workers per retired person will decline substantially by 2050:

Current	5.2
Low population	1.9
Medium population	2.4
High population	3.3
- Per capita cost of health care increases as the population ages
- Fewer workers reduce provincial revenue growth associated with employment, hence sustainability of health care is threatened if health care costs continue to be paid on a pay-as-you-go basis

Pre-Funding

- Saving or investment strategy that works with an insurance plan to minimize effect of:
 - Rising premiums associated with inflation
 - Increased health service utilization
 - An aging population
- Collect more through premiums than paying out, creating a reserve
- Reserve grows through investment income and additional surplus premiums
- When rising health care costs exceed the premiums collected, use reserve to pay costs, minimizing the effect of rising costs

Pre-Funding Example

Projection Length

- Long-term projections are required to assess sustainability as the full effects of an aging population do not occur until after 2040
- Variability in growth rates, particularly health services inflation, has enormous cumulative impact over the projection period
- Projections are linked to common assumptions where possible – ensuring consistent relative ranking of options despite variability in absolute values
- Economic model runs to 2025 – matching the length of the province's 20 year plan

Prescription Drugs

Prescription Drugs – Methodology Notes

- Funded by Government of Alberta, private insurers and employers and out-of-pocket payments by individuals

Population Group	Current Cost	Population
For current beneficiaries of <ul style="list-style-type: none">• Alberta Health and Wellness• Alberta Human Resources and Employment (AHRE)• Alberta Seniors and Community Supports	Claims costs established by therapeutic class, age and gender cell using detailed drug claims paid in Fiscal Year 2004 to 2005	Demographic composition covered by AHRE and Alberta Seniors and Community Supports corresponds to population of claimants
Employer Insured	Therapeutic class, age and gender cell costs of a large employer plan used Costs adjusted to balance CIHI data	Total population less those covered by Government of Alberta and those uninsured
Uninsured / Underinsured (27% of population)	Cost assumed equal to those of the average population (for the same age and gender)	Demographics derived from the Canadian Community Health Survey (CCHS)

- Inflation rates and utilization trends for each therapeutic class of drugs created taking into account the projected impact of anticipated cost control mechanisms
- Cost projections created by combining drug costs, anticipated utilization and projected population data

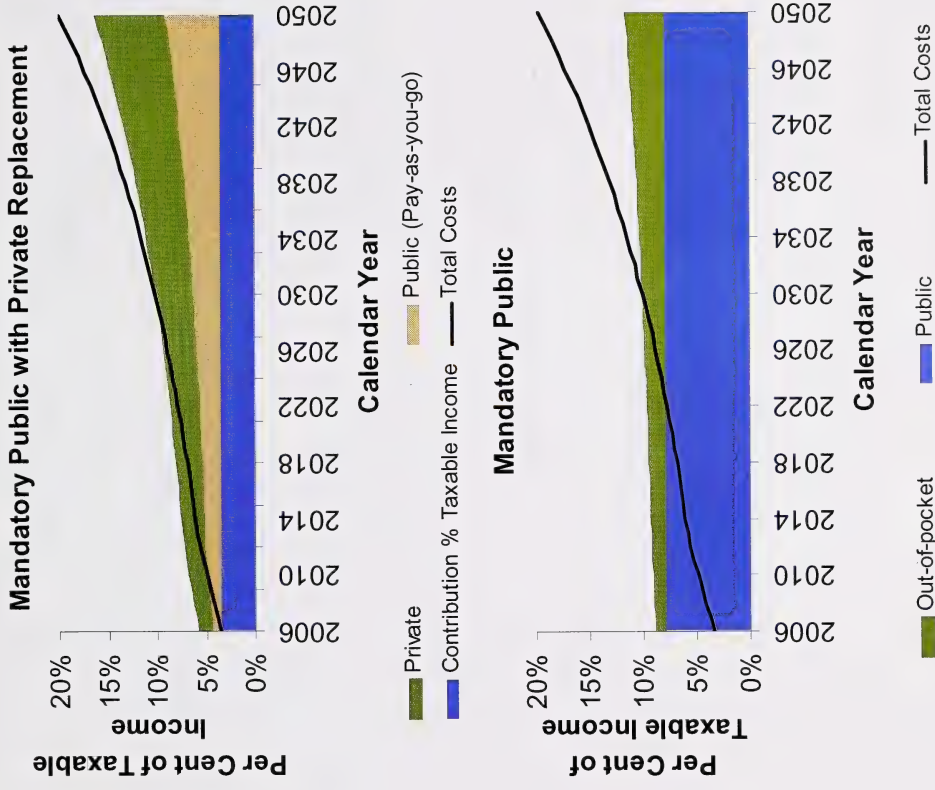

Adjusted Baseline Cost Projection

- Adjusted to assume a number of cost control mechanisms
- Otherwise the cost of prescription drugs will exceed total taxable income in 2036
- Public drug programs may be difficult to cost-effectively transfer to private insurers due to potential for large liabilities
- Using reasonable control mechanisms, costs expressed as a percentage of taxable income will more than quadruple by 2050

Mandatory Drug Plans with Pre-Funding

- Mandatory drug plans were selected for modelling to:
 - Ensure entire population has drug coverage
 - Prevent free-rider phenomenon where drug insurance is not taken by some of the population
- Public funding can mix pre-funding and pay-as-you-go
- Higher proportion of pre-funded costs increases the up-front burden, but reduces peak cost (relative to taxable income)
- The mandatory public with private replacement model assumed seniors and special support plans would be payable by entire population

Sensitivity Testing

- Population growth and working proportion of the population has material impact on costs relative to total income, particularly after 2030 when aging effects become increasingly important

- Rapid implementation of cost control mechanisms has dramatic short and long term effect on drug costs

Conceptual Model Comparison

Conceptual Model	Encourage Personal Responsibility	Efficiency	Cost Control	Choice in Coverage
Public Mandatory	Contingent on plan design (premiums and cost sharing)	Limited competitive pressures	Single purchaser with higher buying power	Limited
Public Mandatory with Private Supplemental Coverage	Contingent on plan design (premiums and cost sharing)	Limited competitive pressures	Single public purchaser with higher buying power	Limited for basic Higher for supplemental
Public Mandatory with Private Replacement Coverage	Contingent on plan design (premiums and cost sharing)	Strong competitive pressures for private plans (effect limited with global suppliers)	Private purchasing impacted by public cost control methods	Higher
Private Mandatory with Public Premium Pooling	Contingent on plan design (premiums and cost sharing)	Strong competitive pressures (effect limited with global suppliers) Centralized premium collection Decentralized administration	Private purchasing impacted by public cost control methods	Higher

Prescription Drugs Health Insurance Observations

- Mandatory coverage ensures everyone contributes financially for the benefit they receive
- Combination of private and public coverage allows employers to offer higher coverage where desired
- Province-wide cost control mechanisms required to control total costs
- Effect of single purchaser in setting prices is materially important
- Public mandatory insurance with private replacement coverage is similar to the model used in Quebec, therefore Canadian experience in implementation is available

Continuing Care

Continuing Care – Methodology Notes

- Baseline projections based on Scenario 2 of Alberta Health and Wellness Regional Continuing Care Model (RCCM)
 - Assumes a “medium-shift” from facility-based services to community-based services
- RCCM cost projections were revised in the following ways:
 - Alberta Finance’s medium population projection revised to reflect anticipated improvements in mortality rates
 - Unit costs inflation increased to 4% to reflect anticipated trends
 - Percentage of total funding allocated for capital expenditures increased to recognize obsolescence
 - Expected costs from implementation of “What We Heard & Draft Recommendations” produced by Task Force on continuing care incorporated
- Accommodation and care are decoupled – only the health care portion of this is modelled for insurance
- As an insurance policy, it is assumed that once a certain level of disability exists, requirement to pay premiums stops, irrespective of whether home or facility-based services are provided

Continuing Care – Premium Base

- Spreading the cost over a portion of, or the entire population, impacts the insurance premium
- A smaller number of premium contributors will have to make a larger payment

Population Sensitivity

- Aging and proportion of total population in workforce are primary drivers of cost relative taxable income
- Inflation is a material factor where health care salaries rise faster than those of general population

Continuing Care – Cost Impacts

- Total costs are relatively similar with different insurance models
- Private supplemental insurance would increase total costs on a supply and demand basis
- Uptake of existing supplemental products has been very low in Alberta and other markets (as insurers limit benefits to control risk)
- Private costs are more likely to be paid out-of-pocket as incurred
- Full or partial pre-funding is highly appropriate as cost projection factors have relatively little variance because they are largely salary driven

Conceptual Model Comparison

Conceptual Model	Encourage Personal Responsibility	Efficiency	Cost Control	Choice in Coverage
Public Mandatory	Contingent on plan design (premiums and cost sharing)	Limited competitive pressures (depends on private providers of continuing care)	Single purchaser with higher buying power	Limited
Public Mandatory with Private Supplemental Coverage	Contingent on plan design (premiums and cost sharing)	Limited competitive pressures (depends on private providers of continuing care)	Single public purchaser with higher buying power Limited private services with total cost set by market forces	Limited for public component Private has not had many offerings in other markets
Private Mandatory with Public Premium Pooling	Contingent on plan design (premiums and cost sharing)	Competitive pressures on cost, regulation required to ensure quality Centralized premium collection Decentralized administration	Overall total Private Mandatory costs determined by the public pool funding Costs for enhanced insurance policies are supply/demand driven	Possibly more coverage; dependent on regulatory requirements

Continuing Care Insurance Observations

- Pre-funding is a continuing care savings plan for an aging population:
 - Requires mandatory participation
 - Premiums linked to income limit inflation risk
- Insurance options have less impact on cost than operational improvements
 - Both are smaller than the aging effect

Non-Emergency Health

Non-Emergency Health – Methodology Notes

- All non-emergency health services are funded by Alberta Health and Wellness
 - Non-emergency services not a separate category of services
 - Protocol created to identify services that would be considered non-emergency for purposes of the analysis
 - Used nationally recognized triage score for emergency room visits to differentiate emergency from non-emergency
 - Scores of one or two with treatment regarded as emergency; falls outside the scope of the analysis
 - All other treatments considered in the analysis of non-emergency services
- Per capita claims rates developed directly from Alberta Health and Wellness data
 - Annual projection factors developed from public sources
 - After ten years, initial factors were reduced to 6% per year under the mandatory public scenario (or actual factor if already less than 6%)
 - Resulting per capita claims multiplied by projected population in each future year
 - Generated projected future annual claims

Baseline Cost Projection

- Total projected costs were \$5.1 billion in 2006
- By end of projection period:
 - Cost inflation and population growth combined to \$245.8 billion
 - As a per cent of projected taxable income, claims grew from 5.5% in 2006 to 37% in 2050
- Public mandatory insurance will follow baseline scenario, but with lower projection factors after 2015 because of the assumed 6% cap on cost increases

Federal Funding

- Federal transfers are a large component of non-emergency health funding
- Assuming the transfers grow at 6% per year, federal transfers will decline as costs grow faster due to
 - population growth
 - aging and
 - inflation
- Any conceptual model with private insurance for non-emergency health may result in reduced federal funding

Sensitivity Testing

- Inflation is the most significant factor impacting projected growth of non-emergency health
- Primary operational factor for ensuring sustainability is controlling cost growth (largely total salaries) through improved productivity

Conceptual Model Comparison

Conceptual Model	Encourage Personal Responsibility	Efficiency	Cost Control	Choice in Coverage
Public Mandatory	Contingent on plan design (premiums and cost sharing)	Limited competitive pressures Centralized administration	Competition between health service providers	Limited
Public Mandatory with Private Supplemental Coverage	Contingent on plan design (premiums and cost sharing)	Limited competitive pressures Mixed administration	Competition between health service providers	Limited for basic Higher for supplemental
Private Mandatory with Public Premium Pooling	Contingent on plan design (premiums and cost sharing)	Strong competitive pressures Centralized premium collection Decentralized administration	Competition between health service providers	Higher

Non-Emergency Health Insurance Observations

- Privatization of providers and potential improvements in productivity could have a larger long-term impact on cost control than private insurance
- Effect of private insurance is limited without private health care providers (little control over costs and limited opportunity to differentiate)
- Use of cost sharing mechanisms (co-payments and deductibles) could reduce costs and may not offset the potential loss of federal funding

Supplemental Health

Supplemental Health – Preliminary Notes

- Broadly defined as a typical group extended health care insurance policy without prescription drug coverage
- Benefits:
 - Paramedical specialists
 - Hospital accommodation
 - Vision care
 - Miscellaneous medical equipment and supplies
- Benefits are largely privately insured; plans typically incorporate deductibles and co-payments
- Current plans negotiated between insurers and plan sponsors (employer or union)
- Pricing functions on an annual renewable term basis (no pre-funding)

Baseline Cost Projection

- Total projected costs are \$2 billion in 2006
- Cost inflation and population growth drive this to \$115 billion by 2050
- Per cent of taxable income grows from 2.2% to 17.25%
- Equivalent level funding percentage is 7.76%
- 15% of costs are currently paid through various government programs

Sensitivity Testing

- Economic impacts (low economic growth) and claims costs (high inflation) have greatest impact
- For supplemental health, long-term inflation risks are currently borne by private industry

Conceptual Model Comparison

Conceptual Model	Encourage Personal Responsibility	Efficiency	Cost Control	Choice in Coverage
Private optional	Contingent on plan design (premiums and cost sharing)	Sold in a very competitive marketplace	Limited – multiple purchasers with total cost set by market forces	High, but may be determined by employer
Private Mandatory	Contingent on plan design (premiums and cost sharing)	Sold in a very competitive marketplace	Limited private services with total cost set by market forces	High

Supplemental Health Insurance Observations

- Mandatory coverage ensures coverage for all and that everyone contributes financially for the benefit they receive
- With mandatory public insurance, the province would incur additional costs, given that these benefits are currently privately insured
- Private carriers have no greater incentive to control costs than at present
- Currently, cost risk is borne by private industry
- Mandatory coverage requires government oversight

Economic Model

Economic Model Approach

- System dynamic technique to link three distinct types modules:
 - General economic – based on relationships in Alberta Finance’s long-term economic projections
 - Public finance – projecting revenue and costs forward with relationships developed from income statement and stated policy, linkages to general economic performance, and health care projections
 - Health care (public and private) – based on actuarial projections and Statistics Canada data
- Seventy assumptions to adjust where analysis requires
- Validated against:
 - Key relationships remaining relatively steady over time when causal links were not impacted
 - Results similar to BMO Special Report on “Alberta’s Long-range Outlook” (January 4, 2006) for general economy and public finance

Note: All financials presented in calendar years

Baseline – Revenue and Expense

2016

- 50% of provincial expenses are health care
- Projected annual deficit and impacts sustainability

Projected Fiscal Summary 2005 to 2025
Provincial Income Statement
 (Millions of Dollars)

	Current Situation				
	2005	2010	2015	2020	2025
Revenue					
Personal provincial tax	\$ 5,062	\$ 7,162	\$ 10,737	\$ 15,893	\$ 23,163
Business provincial tax	\$ 2,372	\$ 2,633	\$ 3,829	\$ 5,537	\$ 7,945
School property tax	\$ 1,268	\$ 1,417	\$ 1,643	\$ 1,905	\$ 2,208
Other tax revenue	\$ 1,920	\$ 2,444	\$ 3,347	\$ 4,557	\$ 6,156
Resource revenue	\$ 12,307	\$ 10,568	\$ 9,075	\$ 7,793	\$ 6,692
Investment income provincial revenue	\$ 1,404	\$ 2,674	\$ 3,068	\$ 2,610	\$ 897
Other own source revenue	\$ 4,114	\$ 5,238	\$ 7,171	\$ 9,762	\$ 13,187
Federal government transfers	\$ 3,413	\$ 4,409	\$ 5,900	\$ 7,895	\$ 10,566
Provincial revenue	\$ 31,859	\$ 36,547	\$ 44,772	\$ 55,952	\$ 70,815
Expense					
AHW Expense	\$ 8,879	\$ 13,733	\$ 20,260	\$ 29,489	\$ 43,072
Health (other programs)	\$ 771	\$ 1,139	\$ 1,750	\$ 2,880	\$ 5,080
Total Provincial health care funding	\$ 9,650	\$ 14,872	\$ 22,009	\$ 32,369	\$ 48,152
Education	\$ 6,482	\$ 7,922	\$ 9,711	\$ 11,828	\$ 14,296
Social services	\$ 2,530	\$ 3,140	\$ 3,848	\$ 4,687	\$ 5,665
Other expense	\$ 6,298	\$ 7,139	\$ 8,751	\$ 10,659	\$ 12,883
Debt servicing cost	\$ 317	\$ 251	\$ 251	\$ 251	\$ 251
Total Provincial Expense	\$ 25,277	\$ 33,323	\$ 44,570	\$ 59,794	\$ 81,247
Assets					
Net Financial Assets beginning of year	\$ 16,580	\$ 39,056	\$ 46,947	\$ 37,770	\$ 3,509
Capital Assets beginning of year	\$ 10,640	\$ 12,850	\$ 15,224	\$ 17,976	\$ 21,167
Net Assets beginning of year	\$ 27,220	\$ 51,907	\$ 62,171	\$ 55,746	\$ 24,676

- Net financial assets positive for last year

Baseline – Health Care

- Increase in private sector costs largely associated with high prescription drug cost inflation

Projected Fiscal Summary 2005 to 2025

Health Care Funding (Millions of Dollars)		Current Situation			
Funding		2005	2010	2015	2020
Public					
Alberta Health and Wellness	\$	8,879	\$ 13,733	\$ 20,260	\$ 29,489
Other departments	\$	771	\$ 1,139	\$ 1,750	\$ 2,880
Total Health Care Public Funding	\$	9,650	\$ 14,872	\$ 22,009	\$ 32,369
Private					
Insurer funding	\$	1,984	\$ 4,077	\$ 7,021	\$ 10,591
Out-of-pocket	\$	1,192	\$ 2,277	\$ 3,690	\$ 5,462
Total Health Care Private Funding	\$	3,176	\$ 6,354	\$ 10,711	\$ 16,053
Total Health Care Cost	\$	12,827	\$ 21,226	\$ 32,721	\$ 48,422
Use of Funds					
Prescription drugs cost	\$	2,735	\$ 5,698	\$ 9,316	\$ 13,697
Continuing care cost	\$	1,263	\$ 1,749	\$ 2,269	\$ 3,196
Non-emergency cost	\$	4,714	\$ 7,378	\$ 11,454	\$ 17,793
Supplementary health cost	\$	1,830	\$ 3,621	\$ 6,221	\$ 9,402
Other health care	\$	1,900	\$ 2,317	\$ 2,929	\$ 3,710
Total Health Care Cost	\$	12,827	\$ 21,226	\$ 32,721	\$ 48,422
Total Reserves	\$	-	\$ -	\$ -	\$ -

GDP Growth Impact

- Baseline assumption is for GDP growth of 2.5% per year (conservative)
- If a 3.5% per year rate is assumed, overall provincial budget is sustainable through the projection period of 2025

Other Policy Implications

- Large scale pre-funding through increased premiums, shifts consumption to savings. How and where the reserve is invested can substantially impact overall economic performance
- Growing demand for continuing care and non-emergency health will require a dramatic increase to the workforce unless productivity rates increase substantially
- Since the working population will grow at a slower rate, there is potential for shortages and increased wage pressures
- Specific design elements of insurance plans and policies can shift the cost burden between various stakeholders as desired by policy objectives

Final Comments

Final Comments

- Insurance does not intrinsically make health care sustainable through cost reduction, but it supports:
 - Competition between health care providers on cost and quality
 - Pre-funding to reduce the 'peak' cost burden
 - Financial mechanisms to encourage healthier lifestyles and reduced health care usage
- Sustainability requires implementation of cost control measures, ideally done through increasing productivity
- Where an insurance plan transfers risk between the private and public sectors, careful consideration of impacts and potential unintended consequences is necessary
- Consumer choice increases with multiple insurers, each offering different coverage to meet different market needs

Introduction

This document contains advice, proposals, recommendations, analyses or policy options developed for the Minister of Alberta Health and Wellness, and/or department of Alberta Health and Wellness.

Overview

In an effort to improve Albertans' access to quality health care, Alberta's health system changed considerably during the past decade. Stakeholders have worked together and have accomplished a great deal. However, there are still important challenges to address. In response to these challenges, Alberta has announced the Third Way. Overall goals of the Third Way include:

- Improving the health of Albertans;
- Improving access to health care services;
- Providing quality health care services;
- Offering choices to Albertans; and
- Ensuring sustainability of the health care system.

The *Health Benefit Design Options* project supports Alberta's Third Way initiative. This document provides actuarial and economic projections of insurance models for subsequent policy analysis by government. Models and projections were developed for the following health benefit groups:

- Prescription drugs;
- Continuing care;
- Non-emergency health care; and
- Supplemental health care products and services.

Project Deliverables

The overall goal of the *Health Benefit Design Options* project is to explore strategies to contain public health expenditure growth and provide the opportunity for Albertans to have increased access and choice with respect to health care services.

More specifically, the project explores alternative financing models for health services by:

- Creating conceptual models for health services insurance;
- Conducting actuarial analysis of the new models; and;
- Assessing the economic impact of each model.

Conceptual Models

Conceptual models of insurance plans in this study were developed to illustrate some of the options available to the Government of Alberta. They represent a variety of different funding and benefit structures and different approaches to introduce insurance principles into the Alberta health care system.

The conceptual models are based, in part, on the experiences in other provinces and countries (e.g., Quebec, Australia, Germany and the Netherlands), the private sector, and even other types of insurance (e.g., auto insurance). All models are adapted to reflect the specific needs of the Alberta health care system.

Where appropriate, specific insurance plan design attributes have been incorporated into the models. Many can be implemented in any conceptual model, others are variants on specific models for specific groups of health services.

Actuarial Models

The actuarial model and analysis describes the capacity of the current and forecasted Alberta population to cover costs of insurance plans identified during conceptual model development.

Also included in the actuarial model is a funding model that tests assumptions and plan design elements specific to each model. This is a core tool for sensitivity testing. For those specific insurance plans deemed material, and of interest to the Government of Alberta, the impact is modelled where there is sufficient reliable data available.

Economic Model

The economic model is a simulation of the current and forecasted Alberta health care system. It integrates the demographic, utilization and cost data in the actuarial model with:

- Health sector model of funding and labour use;
- Public sector projections based on the functional health structure in the Province's budget; and
- A general economic model derived from Alberta Finance's long-term projections.

Projection Uncertainties

The long-term nature of the projections magnifies the uncertainty inherent in any actuarial and economic projection. While every reasonable effort has been taken to ensure the accuracy of the projections, it is important to note that the reliability of very long-term projections is somewhat limited.

Nevertheless, the funding issues surrounding health care related to demographic shifts are relatively predictable. These shifts are also sufficiently large that early planning is required.

Corrective Model Design

To minimize the impact of statistical uncertainty, assumptions have been linked together where possible. For example, where an assumption proves invalid, it will impact both costs and revenues, minimizing the relative difference between alternatives – if one option is superior to another, the invalidated assumption will not change the analysis, even if the precise calculation and forecasts require revision.

Similarly, the economic modelling has been done as a simulation, rather than a traditional multivariate projection, as the policy changes and potential for changes in causal relationships are too high to ignore.

Inflation

Projected inflation rates for health care service costs are the largest source of uncertainty. Health care spending in Alberta has more than doubled in the last ten years, after remaining relatively stable during the previous ten years.¹ It is not possible to separate the policy and market forces from the rapid increase, nor to assess precisely how the medical inflation rate will change as health care sustainability becomes increasingly at risk in North America and the Organization for Economic Co-operation and Development (OECD) countries.

Indeed, the current inflation trends are not sustainable, and projecting them forward is not a useful process. The Conference Board of Canada's recent study on Ontario's health care system also found it necessary to trend the inflation costs down from current levels (even where there is no evidence that there are management initiatives to justify the assumption). Without this adjustment, health care is unsustainable.

Policy Neutrality

There is no intention that the projections and analysis in this document recommend any specific or general policies to the Government of Alberta. Projections and analysis are, to the extent possible, value and policy neutral. This report is limited to a technical analysis of demographic, health service utilization, cost projections and other economic factors.

This study was funded by Alberta Health and Wellness. The study represents the opinions of the authors who are solely responsible for its contents. It does not represent government policy.

Conceptual Models

This document contains advice, proposals, recommendations, analyses or policy options developed for the Minister of Alberta Health and Wellness, and/or department of Alberta Health and Wellness.

Overview

This section provides a variety of different conceptual models of insurance plans for the Government of Alberta to consider. Each model represents a different funding and benefit insurance structure for providing insurance in the Alberta Health Care System.

Each conceptual model:

- Can stand alone or be combined with any other plan selected for other health services groups;
- Has no implementation interdependencies between other conceptual models presented in this report (although there may be scale or other efficiencies associated with implementing more than one model at a time);
- Provides for the continued delivery of health services programs for all eligible Alberta residents, regardless of their ability to pay;
- Is supported by actuarial models that describe the costs of the health services, both to government and to participating insured persons, over time, and according to a forecasted demographic description of the Alberta population; and
- Simplifies the complexity of an actual health insurance system with many operational mechanisms not fully represented.

Conceptual Models

Six conceptual models were identified through collaborative evaluation against overarching policy objectives for more detailed investigation for at least one health benefit group:

- Mandatory Public Health Insurance;
- Mandatory Public Health Insurance with Private Supplemental Coverage;
- Mandatory Public Health Insurance with Private Replacement Coverage;
- Mandatory Private Health Insurance with Public Premium Pooling;
- Mandatory Private Health Insurance; and
- Optional Private Health Insurance.

Evaluation Criteria

Each conceptual model was evaluated on how effectively it promotes the province of Alberta's health care objectives. Three classes of objectives were identified for the purposes of this project:

- Personal responsibility;
- Efficient care; and
- Cost control.

Personal Responsibility

The models were evaluated based on the degree to which each insurance plan conceptual model encourages citizens to take personal responsibility for their health and the outcomes (lifestyle and financial) associated with personal decisions.

Note that factors beyond an individual's control (such as family history of disease) would not be included in this evaluation of plan effectiveness, even if they impact an individual's risk levels.

Efficient Care

The conceptual models were assessed on their ability to promote efficient delivery of health care. This is largely related to how well each specific conceptual model:

- Promotes the use of cost-effective treatment by promoting, for example, positive health outcomes and wellness, with minimal cost; and
- Reduces unnecessary or not cost-effective treatment (e.g., shopping for diagnoses, substitution of more expensive drugs where there is no clinical evidence of better outcomes).

To this end, the ability to promote improved operational management and competitive pressures is a significant advantage for any of the insurance plan conceptual models.

Cost Control and Sustainability

Models were also evaluated based on their ability to control rising health care costs. Specifically, how well do plans limit the demand and increase the supply of health care services?

Assessment of conceptual models includes both direct and indirect impact.

- *Direct impact* – How does the contribution of an insurance plan (based on a conceptual model) directly impact cost savings? These savings are intrinsic to the operation of the plan.
- *Indirect impact* – What cost control mechanisms can be implemented if this conceptual model is in place? Essentially, how does the model's structure or characteristics allow for other cost control programs?

Furthermore, the conceptual models need to reduce long-term health care costs and support sustainability in the following ways:

- Public health care costs should not grow excessively, threatening the ability of the Government of Alberta to support other provincial programs.
- Total public and private health care costs should not grow excessively to threaten the economic well being of Albertans. The proportion of total

spending devoted to health care should remain as close to current levels as possible.

Finally, a conceptual model's cost control mechanisms are only acceptable if they do not disadvantage population groups that currently receive support from the province of Alberta (e.g., children living in poverty or the disabled).

Preliminary Comments

The conceptual models share a number of common characteristics and properties discussed below.

Health Insurance

As the conceptual models are all health insurance plans, they have a number of common attributes. In this section, the basic principles of health insurance, paying premiums and the effect of competition are discussed.

What is health insurance?

Health insurance spreads risk across a large group of individuals, limiting each member's maximum financial exposure related to the provision of necessary health services (e.g., filling a drug prescription to treat illness).²

The following statements illustrate how this works.

- For individuals, the timing and need for health care services over a lifetime is largely uncertain.
- The cost of providing health care services is also uncertain in terms of timing and magnitude. This

creates a potential risk that an individual who requires very costly health care would be unable to pay health care costs.

- However, for a large group, such as the population of Alberta, the timing, need and cost of health services are relatively predictable.
- Health insurance allows payment of premiums into a funding pool that is used to pay for covered medical services as needed. Since the cost of health care services for the pool is relatively predictable, everyone shares risk.

How can everyone afford to pay premiums?

Premiums are collected using a number of different processes, each with different implications. There are several techniques available to ensure that the collected premiums are sufficient to cover the anticipated cost of health care:

- Governments can pay premiums on behalf of those members of society without the means or capacity to make payments on their own;
- Other income support plans may be adjusted to incorporate the need to pay health insurance premiums; and
- Health insurance premiums can be linked to taxable income. If you do not earn taxable income, then you do not pay health insurance premiums. Those with higher income levels contribute more,

in a manner similar to the income tax system. This particular method for calculating a public sector insurance premium is the most common approach where the public sector is involved in providing health insurance.

Premium Types

Health insurance premiums in different countries are structured in different ways to meet the requirements of local policies. Three general types were identified:

- Fixed dollar premium – a standard rate (e.g., \$750 per year) is levied to provide health insurance coverage;
- Percentage of taxable income – the health insurance premium is based on taxable income (e.g., 1%) and may, or may not, have a maximum amount; and
- Progressive rate of taxable income – the health insurance premium is based on taxable income, but the rate increases as income rises (e.g., 1% for taxable income below \$40,000 and 2% on taxable income above \$40,000). There may, or may not, be a maximum amount of premium paid.

The collection of health insurance premiums may require adjustments to other provincial revenue streams to balance the effects of new income sources.

Projections in this study rely on the total premium collected and do not evaluate the specific policy implications of the different premium types.

Health Care Providers and Delivery

The conceptual models identified in this study are suitable for implementation in environments with different health care delivery ownership structures. Accordingly, each conceptual health insurance model could be implemented with health care providers owned by the public sector or private sector.

An insurance provider optimizing the cost-benefit of premiums and health services focuses on measures of service effectiveness (cost, efficiency, quality and similar performance attributes), rather than ownership. If the ownership structure impacts cost effectiveness, it has a material impact on health costs and premiums.

Effect of Competition

Competition between health insurance providers takes place on the following levels:

- Premium rates;
- Services and procedures covered;
- Speed of care delivery; and
- Flexibility and choice.

To the extent that health insurance carriers can make individual supplier arrangements with a variety of health care providers, they are better able to offer a wide range

of plans, each offering different attributes more targeted to the needs of specific population segments.³

For example, an insurance provider could contract with a specialty diagnostic lab and guarantee an MRI within 72 hours from a specialist's request. This would be offset by the need for the patient to visit a specific lab. Consumers would then be able to make choices between plans such as this, and others that offer greater flexibility in selecting providers, but have longer wait times.

Therefore, if there are only public-sector health care providers (or only public-sector providers for a large group of health services), it is difficult to create a range of insurance plans as there is likely limited variation in health service delivery.

Community Rating

Within the context of health insurance, community rating means that an insurance company must charge the same premium rate for a given level of service, regardless of age, sex or health status. Essentially, all adults pay the same amount for the same benefits (subject to linking premiums to income level, where everyone at the same income level would pay the same premium).⁴

All of the conceptual models where insurance coverage is mandatory (i.e., everyone in the population must participate) can accommodate community rating as an attribute of specific insurance plan design.

This approach does not generally work for plans where coverage is optional, as individuals who are more likely to

need health services and make claims are more likely to purchase insurance. Those in low risk groups generally take on lower levels of coverage. The net effect is to increase the cost of insurance to those most likely to need it.⁵

Unlike auto or life insurance, individual attributes such as age, sex, health or past claims do not affect premium rates. Thus, while ensuring equal premiums and shifting costs across the entire population, community rating precludes setting premiums in a manner that encourages wellness and healthy lifestyles (which in turn reduce the overall health care costs).

One example for using community rating would be to ensure that the differential cost of health services between genders does not create different premium costs. Simply, without community rating an insurer would offer different rates to men and women. As noted above, to effectively price a flat insurance rate for the entire Alberta population regardless of gender, an insurance plan should be mandatory.

Risk Pooling

Where public policy requires community rating or a limited number of individual attributes for setting premiums, there is a risk that private insurers will 'select' their clients. That is, the insurer seeks to obtain clients with a risk profile that is lower than is commensurate with the premium charged. This will increase profitability for the insurer.

To minimize the effect of this, and focus competition on providing cost-effective insurance with appropriate consumer choice, risk pooling could be introduced for the mandatory private health insurance models. Essentially, a funding pool is created and those insurers with lower risk are required to pay into the pool, and those with higher risk clients are entitled to take funds out. This approach, or a variant on it, is currently used in several countries, including Switzerland and the Netherlands.

Cost Management

Insurance providers use a number of techniques to manage health costs. There are two common techniques that can be used with any of the conceptual models – cost sharing and treatment protocols.

Cost Sharing

Cost sharing means that claimants must make payments towards the insured health services they use. Co-payments and deductibles are two forms of cost sharing. Insurance providers use these cost sharing techniques to ensure that claimants are aware of the cost associated with health care, and to limit unnecessary demand by making the claimant partially responsible for payment of the health service.⁶

While similar in principle, the two techniques differ in detail:

- *Co-payments* – a claimant pays either a percentage of the cost or a fixed fee – each time they receive a health service and;
- *Deductibles* – the claimant pays up to a certain amount, making the claimant the first payer. The insurance provider does not pay for the health service until the costs exceed the deductible value.

These mechanisms may be further modified by introducing different minimum and maximum payment levels. For example, some plans specify that total co-payments or deductibles paid cannot exceed a defined maximum in a specific year.

Note that for health services included in the *Canada Health Act*, co-payments and deductibles may attract penalties or the withholding of transfer payments.⁷

The effectiveness of co-payments and deductibles is controversial in the health care arena. Proponents suggest that co-payments and deductibles reduce citizens' sense of entitlement toward health care, limiting demand and placing greater responsibility on individuals to adopt healthy lifestyles. They encourage people to only use the health care system when there is an appropriate need. Without cost sharing, people tend to overuse health care as it is inexpensive to access, but expensive to deliver. Critics use research evidence to suggest that these objectives are not reached in practice, and although health care demand is reduced through co-

payments, it fails to target the kind of health care use that strains the system. For example, patients with colds that are untreatable by physicians tend to reduce their use of the health care system in the same proportion as patients with hypertension, who should be seeking urgent medical attention.⁸

Treatment Protocols

Insurance providers can use treatment protocols for specific health services to standardize medical care, raise quality of care, reduce risks and balance cost and medical outcomes. These protocols often consist of a set of decision points and recommended (or mandated) choices for specific courses of treatment.

From the cost control perspective, initial treatment is often the lowest cost/best-outcome combination. If initial treatment is inappropriate or ineffective, there is a list of successive options to consider. Taken together the protocols attempt to optimize the trade-offs between cost and effectiveness.

On one hand, health care providers often resist these protocols on the grounds that only the attending professional has all of the facts available to make a decision and select a course of treatment that best meets the needs of the specific patient.

On the other hand, health care professionals face difficulties remaining up-to-date on all aspects of health care. There is also a disconnect between prescribing

treatments and paying for care – ultimately, medical professionals may be unable to make the cost-effective decisions required to keep the health care system as a whole sustainable.⁹

Cost Impacts

Where a conceptual model has a private sector component, there is a cost impact. Although the impact varies somewhat for each insurance model and health service, these can be summarized as:

- Increasing costs due to requirement for return on capital and profit, and
- Decreasing costs associated with higher productivity associated with trend to increase capital use in the private sector.

Pre-Funding

Pre-funding refers to a saving or investment strategy that works in conjunction with an insurance plan to minimize the effect of rising premiums associated with inflation, increased health service utilization and an aging population.¹⁰

Pre-funding refers to a saving or investment strategy that minimizes the effect of rising premiums associated with inflation, increased health service utilization and an aging population.

Essentially, pre-funding collects more premiums and other income than there are anticipated costs, creating a reserve. Over time, this reserve grows through investment income and additional surplus premiums. Then, at a future point when rising health care costs exceed the premiums collected, funds in the reserve can be used to pay costs, minimizing the effect of rising costs.

The pre-funding rate needs periodic recalculation to reflect variations between projections and actual experience. Also, if the pre-funding interval is shortened, the impact on mitigating the rate of costs decreases and the rate structure resembles a pay-as-you-go approach.

The above pre-funding example shows how the rate of increase in costs is higher than the increase in premiums. Indeed, while costs nearly double in the example, the premiums rise by only 20% as the reserve and subsequent investment income fund a portion of costs once premiums are unable to do so. Thus, although costs

are not contained in the example, the “spike” in costs is not as significant a disruption as would otherwise be the case.

Aging Population

Pre-funding is particularly significant where there is an aging population and the proportion of the working population is declining relative to those not working (e.g., retired persons). Based on updated and extended Alberta Finance population projections, the number of workers per retired person will decline from 5.2 to between 1.9 and 3.3 by 2050.¹¹

*The aging Alberta population
will place an increased
burden on workers to support
public health care costs.*

Projected Alberta Population – 65+ / 20-64 ratio

Should health care costs continue to be paid on a pay-as-you-go basis, as is current practice in Alberta, the sustainability of health care is threatened insofar as:

- The per capita cost of health care increases as the population ages (older people use more medical services); and
- Fewer workers reduce the component of provincial revenue growth correlated with employment.

Accordingly, there is a trend of increasing health care costs and reduced revenue growth, which may increase significantly should natural resource incomes decline materially after 2025. In turn, this could impose a dramatically higher financial burden on the post baby boomers to support the health care costs of the previous generation. Indeed, as the demographic bulge (currently between 45 and 62 years old) levels off, subsequent generations would face a relatively lower financial burden.

Pre-funding provides an opportunity to reduce the payment growth rate and allow the baby boom generation to increase contributions to their future health care costs (and reduce the proportionate burden on the following generation).¹²

Health Savings Account

A Health Savings Account (HSA) is a tax advantaged savings plan that allows individuals to deposit money to pay for current and future medical expenses. Generally, money is deposited to the account prior to paying tax, and the account may be drawn upon to pay for medical expenses on a tax free basis. These typically include:

- Full payment of uninsured health services; and
- Co-payments and deductibles for those services covered by insurance.

All of the conceptual models described in this document may be used in conjunction with a Health Savings Account.

Mandatory Public Health Insurance

This plan centres on a single government run, or owned, health insurance provider. Operationally, the insurance plan is set up and run in a manner similar to a private insurer, without needing to generate a profit (unless there is a policy decision to do so).

The core element of the conceptual model is the common funding pool, which is used to pay ongoing costs and create a reserve (for risk management or pre-funding anticipated expenses). Funding sources could include:

Government of Alberta

- General revenue; and
- Health funding from the federal government.

Private Sector

- Individuals are typically the primary contributors to the funding pool. Their contributions could be offset by a reduction in income/other taxes and the current Alberta Health Care Insurance Premium.
- Employers could be required to pay a portion of the premium (this decision may account for the level of funding currently provided by employers for the specific group of insured health services).

Premiums directly from the private sector can be either flat fee or income based. As noted previously, flat fees enable universality with government support for those with low incomes or limited wealth.

Since this model assumes a single government-controlled purchaser of health care (unless individuals can purchase health care directly), provider fees will largely be set through negotiation and/or regulation.

Plan Choice

Choice is limited, as the provider often resembles a monopoly. Although there is no conceptual limitation that prevents offering different plans with a variety of coverage levels, no structural pressure exists to encourage the insurance provider to offer choice.

Administrative Structure

Mandatory public health insurance has a centralized administrative process with a single premium collector and one manager of health care providers.

Canada Health Act

There is no profit element in mandatory public health insurance. Plan design elements, such as cost sharing, could attract penalties.

Transparency of Government Support

Transparency is variable – premiums are distinct from other government support to health care and variations in premiums could be clearly linked to changes in government support (e.g., reduction in federal health transfers directly increases premiums).

Cost Control

Predictability

The Government of Alberta can determine the total level of health care spending in the province. Although limiting

this can impact quality and quantity of care, there is an absolute ability to prevent an undue rise in total costs.

Competitive Pressure

As the mandatory public health insurance model is monopolistic, there are no competitive pressures on plan costs.

Mandatory Public Health Insurance with Private Supplemental Coverage

This type of plan offers two choices of health insurance:

- Mandatory health insurance via a publicly run insurance plan; and
- Optional private insurance plan as a supplement to public insurance.

The public plan provides universal coverage, but citizens have the option of purchasing additional private insurance from a range of providers to ensure supplemental benefits, including faster or additional services. The core element of the public plan is a common funding pool (as in the mandatory public plan), which is used to pay the ongoing costs and create a reserve (for risk management or pre-funding anticipated expenses). Funding sources could include:

Government of Alberta

- General revenue; and
- Health funding from the federal government.

Private Sector

- Individuals are typically the primary contributors to the funding pool. Their contributions could be offset by a reduction in income/other taxes, and the current Alberta Health Care Insurance Premium.
- Employers could be required to pay a portion of the premium (this decision may account for the level of funding currently provided by employers for the specific group of insured health services).

The supplemental plans are paid exclusively through individual or employer private sector premiums, including:

- Individuals who decide they would like to purchase insurance allowing access to a different level of coverage than that in the standard universal plan; and
- Employers that wish to provide employees with additional insurance coverage, to ensure enhanced medical services.

Note that where there is a small set of niche services available for supplemental coverage, it may be difficult to attract a significant level of insurance providers. This scenario assumes that only a small number of consumers will take supplemental health insurance if the range of services covered is small, for the majority will seek coverage only when the risk is realized and the private carrier will not provide coverage (i.e., the illness manifests itself and coverage would be denied for the pre-existing condition).¹³

Regulation

Private plans may require regulation or oversight for solvency and coverage levels. Private plans may also require a community rate or individual premiums based on health risk assessments.

Plan Choice

For publicly provided services, choice is limited by a monopolistic provider. There is no structural pressure encouraging the insurance provider to offer choice.

Private services would operate in a fully competitive environment, and one would expect a range of choice commensurate with market size and variability in customer needs.

Administrative Structure

The public insurance administration is centralized, with a single premium collector and one purchaser of health care services.

In contrast, the private supplemental insurance administration is decentralized, with multiple channels for sales and collecting premiums and multiple purchasers of health care services.

Canada Health Act

There is no profit element for the mandatory public health insurance. Plan design elements, such as cost sharing, could attract penalties.

Transparency of Government Support

Transparency is variable. For the public element of the plan, premiums are distinct from other government support to health care and variations in premiums could be clearly linked to changes in government support (e.g., reduction in federal health transfers increases premiums

directly). Private costs would be clear (and direct) to the extent that they are paid directly (rather than through an employer or other group).

Cost Control

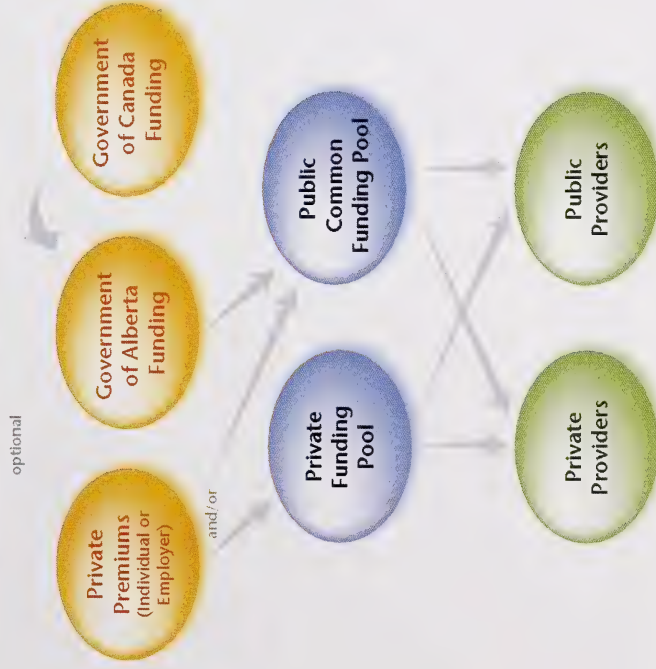

Predictability

The Government of Alberta can determine the mandatory level of health care spending in the province, but the supplemental portion will be subject to supply and demand pressures as would any other consumer service.

Competitive Pressure

The monopolistic nature of the public plan leaves the possibility for competitive pressures on the mandatory portion of plan costs. Supplemental services would have full competition on prices and service delivery.

Mandatory Public Health Insurance with Private Replacement Coverage

This type of plan provides a core level of universal health insurance through a publicly run insurance plan. However, citizens have the choice to replace this coverage with private insurance that meets a defined minimum level of coverage.

This type of plan offers universal coverage and allows for community rates, providing rates are supported by

regulation. Variation in group pricing such as those offered by employers, is also an option.

The core element of the public plan is a common funding pool (as in the mandatory public plan), which is used to pay the ongoing costs and create a reserve (for risk management or pre-funding anticipated expenses). Funding sources could include:

Government of Alberta

- General revenue; and
- Health funding from the federal government.

Private Sector

- Individuals are typically the primary contributors to the funding pool. Their contributions could be offset by a reduction in income/other taxes, and the current Alberta Health Care Insurance Premium.
- To offset the potential issue of high-income earners selecting private insurance, privately provided replacement coverage does not need to result in a complete exemption from premiums.
- Employers could be required to pay a portion of the premium (this decision may account for the level of funding currently provided by employers for the specific group of insured health services).

The replacement plans would be paid through individual or employer private sector premiums, including:

- Individuals who decide that they would like to purchase insurance allowing access to a different level of coverage than that in the standard universal plan; and
- Employers that wish to provide employees with additional insurance coverage, to ensure enhanced medical services.

Plan Choice

Choice in finding a suitable insurance plan would be relatively high as insurance carriers seek to attract business.

Administrative Structure

The public insurance administration is centralized, with a single premium collector and one purchaser of health care services.

The private supplemental insurance administration is decentralized, with multiple channels for sales and collecting premiums and multiple purchasers of health care services.

Canada Health Act

Alignment with the *CHA* principles is dependent on the specific plan design and funding processes. Plan design elements, such as cost sharing and multiple levels of coverage, could attract penalties.

Transparency of Government Support

Transparency is variable. Premiums are distinct from other government support to health care and variations in premiums could be clearly linked to changes in government support (e.g., reduction in federal health transfers increases premiums directly). For private costs, there is no government support.

Cost Control

Predictability

The Government of Alberta can determine the mandatory level of health care spending in the province, but the replacement portion will be subject to supply and demand pressures as would any other consumer service. This may increase total costs if the replacement insurance covers health care of higher quality (and price).

Several factors could drive higher income purchasers to private insurance, leaving the public system with a higher proportion of those unable to afford premiums. The overall impact would see an increase in the need for direct or indirect subsidies to the public plan. It is unclear, however, whether the total public funding for the “at risk” population would increase; specific plan design and funding policies would determine this. As noted previously, individuals selecting replacement coverage may be required to make some payments into the common public funding pool. Nevertheless, the funding

rate needed to provide for public expenses would likely increase.

Competitive Pressure

The presence of private insurance providers fosters competitive pressure in the system. Subsidies to the public sector could distort the market by potentially reducing the size of the private sector, and thus limiting competitive pressure. This would be highly dependent on the actual relative pricing between plans.

Mandatory Private Health Insurance with Public Premium Pooling

With this conceptual model, health care insurance is provided through a privately managed plan, but with premiums provided through a common fund. A similar model was introduced in the Netherlands on January 1, 2006.

Health care recipients have a choice between private insurers that may offer multiple plans, which meet a minimum standard of coverage.

Participation in funding a common public funding pool is mandatory, although individuals and employers have the opportunity to purchase additional insurance beyond coverage funded by the pool. The public funding pool receives payments from both the Government of Alberta and the private sector.

Government of Alberta

- General revenue; and
- Health funding from the federal government.

Private Sector

- Individuals are typically the primary contributors to the funding pool. Their contributions could be offset by a reduction in income/other taxes, and the current Alberta Health Care Insurance Premium.

- Employers could be required to pay a portion of the premium (this decision may account for the level of funding currently provided by employers for the specific group of insured health services). In the Netherlands this level of contribution was set quite high, and there has been a very negative reaction from the private sector who view this as a hidden tax.

Additional coverage could be provided with individual and employer private sector premiums, including:

- Individuals who decide they would like to purchase insurance allowing access to a different level of coverage than that in the standard universal plan; and
- Employers that wish to provide employees with additional insurance coverage, to ensure enhanced medical services.

Payment from the public common funding pool to individual providers is based on either the:

- Risk rating of the specific pool of clients; or
- Costs where the insurers act as administrators on behalf of the public plan.

Regulation

Private plans require regulation and oversight for solvency and coverage levels. The Government of Alberta can determine the mandatory level of health care spending in the province, but the additional coverage is subject to supply and demand pressures, as is any other consumer service.

Private insurers make fee and payment arrangements directly with health care providers, who may be either private or public.

Plan Choice

Choice in finding a suitable insurance plan would be relatively high as insurance carriers seek to attract business.

Administrative Structure

The administration for collecting premiums is centralized; the common funding pool collects all premiums, possibly in conjunction with the income tax system.

Administration of plans is decentralized, with multiple channels for sales and multiple purchasers of health care services.

Canada Health Act

Alignment with the *CHA* principles will depend heavily on the specific plan design and funding processes, particularly the profitability associated with health insurance risk. Also, plan design elements, such as cost sharing and multiple levels of coverage, could attract penalties or the withholding of transfer payments.

Transparency of Government Support

Transparency of government support is variable. For the public portion, premiums are distinct from other government support to health care and variations in premiums could be clearly linked to changes in government support (e.g., reduction in federal health transfers increases premiums directly). There is no public funding for private insurance beyond the core.

Cost Control

Predictability

The Government of Alberta can determine the mandatory level of health care spending in the province, but the supplemental portion will be subject to supply and demand pressures as would any other consumer service.

Competitive Pressure

Pressure exists on administration and health care delivery. Each insurer would like to provide better value for the same premium. To the extent that the insurer holds funds, cash management is a potential area of competitive pressure.

Mandatory Private Health Insurance

In this conceptual model, plan design and/or benefits are mandated by the government but the coverage is purchased directly by individuals or by employers acting on their behalf. Groups who are unable to obtain coverage would require financial support, which would be funded either from the public purse or levied in the form of extra charges to those who can afford coverage.

Plan Choice

Choice in finding a suitable insurance plan would be relatively high as insurance carriers seek to attract business.

Administrative Structure

The mandatory private plan model has decentralized administration with multiple channels for sales and collecting premiums and multiple purchasers of health care services. It would be possible for private insurers to adopt a common claim processing standard to minimize administrative costs.

Canada Health Act

There are several areas where this model may conflict with *CHA*'s principles. However, international experience has shown that universal health care based on mandatory private insurance is possible (e.g., Switzerland).

Transparency of Government Support

Transparency would be limited, as only those receiving government support would be aware that their coverage is subsidized.

Without risk pooling regulation to prevent client selection, universal health coverage is difficult to provide with this model for individuals or groups who are high risk candidates. Although community rating is possible, it would require regulations to ensure that plan purchasers are offered coverage at the same rate regardless of the risk factors. This would increase the risk to the insurer, and there is a high likelihood that this would result in a higher level of premiums to offset this higher risk. Thus, for universal coverage to be practically implemented for this model, a publicly or privately managed risk sharing pool is required.

Cost Control

Predictability

This type of plan has limited ability to directly control cost, with the exception of the level of subsidies provided to various economically or health disadvantaged groups.

Sustainability of this program is variable. It is viable to the extent that market forces are able to contain costs. There is limited capacity to maintain sustainability if the private sector fails to adequately control risks. Sustainability is, to an extent, a function of the private carriers' success in building delivery networks.

Competitive Pressure

Pressure exists on administration, cash management and health care delivery – each insurer would like to provide better value for the same premium.

Cost control is also a function of the private carriers' success in building and managing networks of health care providers.

Optional Private Health Insurance

This is a type of plan where the purchaser negotiates the plan design. Coverage is optional and may be obtained from any private insurer on the market. Pricing is determined by competitive pressures, service delivery costs and profit expectations, as is currently the case, with supplemental health insurance offered in Alberta.

Under this model, there is no universal coverage.

Community rating is not possible for consumers with higher risk characteristics as those requiring greater risk for insurance would force most insurers to materially raise the premiums to unaffordable levels.

Insofar as the basic requirements of insurance models set out for this study, there is limited scope for extending this type of insurance within Alberta.

Regulation

For this model of insurance coverage, regulation is generally limited to solvency, as coverage is optional and there is often little perceived need to monitor corporate plans. Sustainability is variable insofar as those unable to pay do not have to purchase insurance.

Plan Choice

Choice in finding a suitable insurance plan would be relatively high as insurance carriers seek to attract business.

Administrative Structure

Optional private plans are decentralized, with multiple channels for sales and collecting premiums and multiple purchasers of health care services. It would be possible for private insurers to adopt a common claim processing standard to minimize administrative costs.

Canada Health Act

There are several areas where this model may conflict with *CHA's* principles.

Transparency of Government Support

Not applicable.

Cost Control

Predictability

Optional private coverage allows for limited ability to directly control costs, with the exception of the level of subsidies that are provided to various groups (e.g., low income).

Total health services spending is likely limited by market forces – if prices become too high, fewer consumers will purchase. That is, consumers may choose self-insurance, which could become costly in the long run.

Competitive Pressure

Pressure exists on administration, cash management and health care delivery – each insurer would like to provide better value for the same premium.

Cost control is also a function of the private carriers' success in building and managing networks of health care providers.

Prescription Drugs

This document contains advice, proposals, recommendations, analyses or policy options developed for the Minister of Alberta Health and Wellness, and/or department of Alberta Health and Wellness.

Overview

This section is an actuarial projection and analysis of prescription drug care in the province of Alberta. At present, such care is provided both publicly and privately. Public sources of drug care are:

- Alberta Health and Wellness sponsored drug plans;
- Other Alberta ministerial drug benefit programs;
- Alberta government-sponsored drug plans; and
- Indirect Government of Alberta drug spending.

Private sources are largely private insurance carriers and not-for-profit health insurance providers, but 27% of the provincial population are currently not insured under either a public or a private plan.

Analysis identified the primary cost drivers of prescription drugs as:

- Increased drug utilization;
- Drug cost inflation;
- Aging;
- Population growth; and
- Research, which is leading to the creation of new and often very expensive drugs.

Baseline Projection

Current Cost Growth Unsustainable

The rate of increase in Alberta's drug costs is currently around 18%, and the rate of increase is accelerating. A projection was first developed, based on these trends to determine whether this rate is supportable by the economy.

A projection was developed using a base 15% cost inflation rate. This 15% is before aging, population growth and increasing utilization. The base cost projections were then constructed by multiplying the applicable therapeutic class, age and gender cell costs by the projected population. In this scenario, the total public and private drug costs would exceed taxable income by 2036. This is clearly not sustainable.

Baseline – Main Costs Components

Total public private costs exceed 100% of taxable income by 2036. This is not sustainable.

Revised Baseline

Accordingly, the baseline projections used in the actuarial modelling assume the current inflation rate decreases with the introduction of cost and demand control measures. It is assumed that the government will take the driver's seat and enforce a rational and optimal utilization of available drug budgets. The assumption that appropriate measures will be introduced is important, but is only valid if the Government of Alberta introduces measures.

Assuming accelerated implementation of cost and demand control measures, including budget control constraints, the following was built into subsequent modelling. See Considerations for Cost Control Measures later in this section.

Under the constraints, the overall growth rate (that is, including inflation, utilization, population growth and aging) of provincial drug expenses is 18% per year until 2007; then it decreases by 1.5% per annum until it reaches 8% in 2014 and subsequent years.

On this basis, the projected total cost of the existing Government of Alberta drug programs (e.g., drugs for cancer, transplants and HIV) reaches 10% of projected taxable income by 2050, whereas total drug cost reaches 20%. In the graph below, "Private" refers to employer-provided coverage, deductibles and co-insurance amounts paid by beneficiaries, out-of-pocket amounts paid by uninsured individuals as well as costs of over-the-counter (OTC) drugs.

*Total public and private
reach 20% of taxable income
by 2050.*

Total public and private costs reach 65% of provincial revenue by 2050.

The same projected costs, expressed in a percentage of projected provincial revenue, presents an equally challenging view: total drug costs reach 65% of provincial revenue by 2050. Since the public share happens to represent 50% of total drug costs (as seen in the preceding graph), the 2050 projected public costs represent 32% of provincial revenue. Accelerated implementation of budget constraints is not expected to have sufficient impact to produce acceptable long-range results.

Cost growth with these assumptions is still unsupportable in the very long run and additional cost control measures are required.

Model Assumptions

All projections presented below are based on a level of minimum mandatory coverage that must apply to 100% of the Alberta population (except the Canadian Armed Forces, RCMP, federal inmates and others covered by federal government plans).

The minimum mandatory plan design tested includes the following key attributes:

- Current Non-Group benefits (with the current \$25,000 maximum benefit eliminated); and
- A maximum out-of-pocket payment of 3%, 4% and 5% of household taxable income. For this purpose, out-of-pocket amounts include only co-insurance paid on drugs covered by the current Non-Group formulary.

Methodology

To ensure that the entire Alberta population and their projected drug use were included in the cost projections, several sources of data were used to create a complete picture. The following provides a high-level description of how costs and demographic characteristics of populations were determined for both those currently entitled to the various programs as well as those not currently insured for prescription drugs. A more detailed description is contained in the section, Actuarial Methodology, appearing later in this report.

Costs

- Claims costs were established by therapeutic class, age and gender cell using detailed drug claims paid in Fiscal Year 2004-2005 for current beneficiaries of:
 - Alberta Health and Wellness sponsored drug plans;
 - Other Alberta ministerial drug benefit programs;
 - Alberta government-sponsored drug plans; and
 - Indirect Government of Alberta drug spending.
- It was concluded, from a review of the Public Use Microdata File of the Canadian Community Health Survey Cycle 2.1 (2003), that the health characteristics (within a given age and gender cell) of those not currently insured for drugs could be assumed to be the same as those that are insured for prescription drugs. It was therefore assumed that, within each age and gender cell, the costs for the 27% of Albertans currently not insured by a public or private plan were the same as those of the average population.
- For those covered by employer contracts, therapeutic class, age and gender cell costs of a large employer plan were used. These costs were then multiplied by a factor so that total drug costs in Alberta in Fiscal Year 2004-2005 matched the amount derived from CIHI statistics.

Population

In a similar manner, population projections with income and age data were created from multiple sources.

Partial demographic data was available for the population covered by Alberta Health and Wellness. This was completed based on the assumption that it corresponded to the population of claimants but the total was then adjusted to match statistics provided by the Government of Alberta.

- It was assumed that the demographic composition of the population covered by AHRE and Alberta Seniors and Community Supports corresponds to the population of claimants, but the total was adjusted to match statistics provided by the Government of Alberta.
- The demographics of the estimated 27% of the population not covered by existing drug plans were derived from the Canadian Community Health Survey (CCHS).
- The population covered by employer groups was determined by subtracting those covered above from the total population.
- Personal and household income data was provided by Statistics Canada and the Canada Revenue Agency.

Cost Control Assumptions

Three different scenarios were modelled, each representing a different rate of implementation of budgetary cost controls as a level to limit prescription drug costs.

- Under the Immediate scenario, growth was assumed to be limited to 8% in 2008 and beyond.
- Under the Accelerated scenario, growth rates were scaled to reach 8% by 2014.
- Under the Gradual scenario, growth rates reached 8% by 2017.

Scenarios Regarding Possible Budget Targets

Year	Implementation of Budget Constraints ¹			Cumulative Costs	
	Gradual ² (%)	Accelerated ³ (%)	Immediate ⁴ (%)	Gradual	Accelerated
2006	18.0	18.0	18.0	1.00	1.00
2007	18.0	18.0	18.0	1.18	1.18
2008	17.0	16.5	8.0	1.39	1.39
2009	16.0	15.0	8.0	1.63	1.62
2010	15.0	13.5	8.0	1.89	1.87
2011	14.0	12.0	8.0	2.17	2.12
2012	13.0	10.5	8.0	2.48	2.37
2013	12.0	9.0	8.0	2.80	2.62
2014	11.0	8.0	8.0	3.14	2.86
2015	10.0	8.0	8.0	3.48	3.08
2016	9.0	8.0	8.0	3.83	3.33
2017	8.0	8.0	8.0	4.17	3.60
2018	8.0	8.0	8.0	4.51	3.89
2019	8.0	8.0	8.0	4.87	4.20
2020	8.0	8.0	8.0	5.26	4.53

Notes

- Under all scenarios, once the allowable increase of 8% is attained, it remains constant until 2050.
- Allowable increase is reduced by 1% per annum, starting in 2008 until it reaches 8% in 2017.
- Allowable increase is reduced by 1.5% per annum, starting in 2008 until it reaches 8% in 2014.
- The 8% maximum allowable increase applies from 2008.

Scenarios Regarding Possible Budget Targets

It is assumed that 8% as an ultimate inflation rate is realistic based on:

- An assumed general consumer price index of 3% in Alberta;
- An estimated average increase in costs of from 1% to 2% per year resulting from demographic factors;
- Various strategies to optimize drug utilization and control costs; and
- Budgetary caps to ensure the anticipated inflation rate is not exceeded.

There is sufficient evidence to justify the assumption that the Government of Alberta can contain spending to this limit.

Cost control methods include continuing education programs to:

- Reinforce the use of first line therapies with evidence of effectiveness along with evidence of cost and cost-effectiveness to most patients;

- Promote better control over second and third line therapies (mostly single-source drugs subject to prior authorization, step therapy or lower levels of reimbursement); and
- Promote higher levels of awareness of risks associated with replacing drugs with proven safety records by new drugs.

It has also been assumed that the introduction of additional mechanisms will control the cost of prescription drugs in Alberta. These may include:

- Drug plan management
- Electronic claims management and real-time adjudication capabilities;
- Plan design (including sharing and step therapy); and
- Improved purchasing and distribution capabilities

Projections

The base cost projections were then constructed assuming the Accelerated Implementation of budget constraints. The projected population was developed using Low, Medium and High projections already in use by the province. However, these projections were adjusted to account for future mortality improvement according to established actuarial practice.

Per Capita Costs

The next graph represents the per capita costs of prescribed and non-prescribed drugs used in Alberta in 2006. These costs do not include drugs administered within hospitals, long-term care facilities or similar institutions. This is likely the explanation for the reduction in costs at higher ages.

In 2006, 33% of total costs arise from those aged 65 or more. Noting the rapid increase in per capita costs by age and the expectation of an aging population, it is clear that pre-funding is potentially very helpful in providing for the expected costs of public insurance.

Drugs – 2006 Per Capita Costs by Age and Gender

Per capita drug costs rise very steeply with age. One-third of 2006 costs arise from those aged 65 or more. This proportion will increase as the population ages.

Total Cost by Age and Gender – 2006

Overall Age Band	Female	Male	Total
0 - 4	13,532,534	13,330,154	26,862,688
5 - 9	14,762,913	14,435,372	29,198,284
10 - 14	20,287,534	20,137,443	40,424,977
15 - 19	26,109,391	30,737,235	56,846,626
20 - 24	42,242,701	43,084,280	85,326,981
25 - 29	47,948,467	54,941,262	102,889,729
30 - 34	64,172,554	64,660,449	128,833,003
35 - 39	83,366,880	80,255,038	163,621,918
40 - 44	122,879,884	108,775,850	231,655,734
45 - 49	154,040,710	138,652,229	292,692,939
50 - 54	172,101,175	158,455,773	330,556,948
55 - 59	180,392,095	156,545,888	336,937,982
60 - 64	161,865,385	136,676,451	298,541,836
65 - 69	139,845,760	122,597,887	262,443,647
70 - 74	140,479,885	123,425,701	263,905,586
75 - 79	130,926,205	106,315,316	237,241,521
80 - 84	103,174,230	62,386,583	165,560,812
85 - 89	59,288,027	27,726,053	87,014,080
90 +	25,131,139	8,968,353	34,099,491
Total	1,702,547,466	1,472,107,317	3,174,654,783

Population Sensitivity Analysis

Cost projections using the Low, Medium and High population scenario are based on the Accelerated Implementation of budget constraints with respective ultimate increases of 7.5%, 8% and 8.5%. Although a lower population growth results in lower future costs in dollars (it is assumed that the increase is only 7.5% instead of 8%), it also implies an aging of the population and, hence, a slower growth of taxable income. This means that the cost of drugs, when expressed in a percentage of taxable income, is higher under a low population growth scenario.

*Population is an important
cost driver*

Cost Control Implementation Speed Sensitivity

As expected, the speed of implementation of budget constraints has a major impact on projected costs, as illustrated by the following graphs. The three implementation schedules are described in Cost Control Assumptions earlier in this section.

*The choice of the budget
implementation schedule is
crucial to the sustainability of
Alberta's drug costs.*

Mandatory Public Drug Insurance

The mandatory public drug insurance model was the first insurance model adopted for more detailed testing. In this model, the province of Alberta would provide full drug coverage to all Albertans, using sound insurance principles to develop premiums, project costs and manage the plan.

From page 2-12

The assumed plan design is that the current Non-Group benefits (with the current \$25,000 maximum benefit eliminated) is the mandatory plan, applicable to current uninsured individuals as well as those currently covered by employer or union plans. The government-provided coverage and benefits for other persons are assumed to continue without changes except that the current \$25,000 maximum benefit is eliminated for Alberta Health and Wellness drug benefit plan beneficiaries.

This effectively results in a reduction of benefits for individuals currently insured under employer and union plans since these plans are more generous than the current Non-Group benefits. It is assumed that the use of prescription drugs by such persons would remain the

same and that the reduction of coverage would be paid out-of-pocket by beneficiaries.

Note that the relative merit of each model is independent of the assumed plan design. Such a plan would incorporate:

- Deductibles and maximum out-of-pocket amounts vary with the capacity to pay;
- Tiered co-insurance percentages apply; and
- All drugs currently covered by the special drug programs (for instance drugs for cancer, HIV and transplants) are included within the mandatory plan.

However, since the parameters of this ideal plan still need to be determined, it cannot be used in this section to compare the various models.

Cost Projections

In the next chart, "Public (Additional)" refers to the current 27% of the population that are not insured and to the portion of current employer and union plans that correspond to the current Non-Group benefits.

Mandatory Public Drug Insurance – Main Costs Components

Pre-Funding

Pre-funding is a means of stabilizing rising costs over a specified number of years by charging a level premium that is projected to be sufficient to pay the costs over a specified period. (In the projections, the fund is reduced to zero by the end of 2050.) In effect, it averages the costs, so that initial funding contributions exceed current costs, creating a surplus that is run down in later years when costs exceed available funding. The surplus is invested, creating investment income that reduces the cost. Such surplus must be earmarked for payment of future claims.

The level per cent of taxable income basis for expressing the premium is a logical basis to use, because taxable income is a readily recognized index that ensures a reasonable match between required funding and ability to pay. It does, however, have one deficiency – a percentage is not necessarily easy to interpret in dollar terms. Thus, the flat dollar funding contribution per capita that would pre-fund all projected costs to 2050 was calculated. This flat dollar charge gives a useful estimate of the average impact of funding on all Albertans, ignoring differences in income. As such, it

is essentially an average across all income levels and is provided as a rough measure, rather than a recommended approach.

This flat dollar amount is \$2,603 per capita. In determining this amount:

- The flat amount was indexed at 4% per year; and
- Albertans aged less than 16 were excluded from the calculation.

This compares with the level percentage of taxable income specified later in this section (7.98%).

The following graph compares the flat charge with the level per cent charge, using 2006 taxable income, separately for males and females.

With pre-funding, the public share of the cost is a flat 7.98% of taxable income of the entire population. This percentage applies from 2006 to 2050.

If a maximum out-of-pocket cost were included, the

additional cost (expressed in level percentage of taxable income) would be:

Maximum Level	Cost (as a Level Per Cent of Taxable Income)
3% of Household Income	0.37%
4% of Household Income	0.30%
5% of Household Income	0.25%

These relatively low changes are explained by the fact that the Non-Group formulary excludes some expensive

drugs (such as cancer treatment) that are paid by Alberta Health and Wellness special drug programs.

The additional cost for such a maximum would need to be funded from other sources. Examples include an extra premium from the insured population or a contribution from the province's general revenue fund. Note as well that the government would need to determine how to provide the full mandatory coverage for those who could not afford to pay the required premiums.

Sustainability

Pre-funding significantly increases the sustainability of the plan, first by stabilizing the expected cost and second by generating investment income to pay part of the costs. The current pay-as-you-go system does not build up funds to generate investment income, so the aggregate cost to Albertans is higher over time than would be the case under a pre-funding model.

*Total public and private costs
are almost identical to those
of the revised baseline.*

Opportunity for Choice

With a single provider, there is little opportunity for choice.

Opportunity to Link to Behaviour

Linking coverage to behaviour could require differential treatment of Albertans based on health status and lifestyle choices. For example, restricting coverage available to smokers or to the obese would be highly controversial to bring about. Such a decision would require careful policy examination by the province.

Another approach is through plan design, for instance, by having deductibles and other plan features that make users share the financial implications of their drug consumption (which is often driven by lifestyle).

Implementation

Implementation would be complex – the private industry is currently very involved in the insurance and delivery of prescription drug care to Albertans. It can be anticipated that they would not welcome a mandatory public plan that would reduce their premium volumes.

Conclusion

- Mandatory public coverage ensures universal coverage for all Albertans.
- Implementation would be complex and require extensive preparation with the private insurance industry.

- The public model enables Alberta to exercise some degree of cost control by limiting available funding.
- Limiting funding does not in itself limit demand growth.
- The mandatory public model reduces employee and employer choices without materially reducing costs.

Mandatory Public Drug Insurance with Private Replacement Coverage¹⁴

Under this model, it would be mandatory that all Albertans be covered by a prescription drug plan at least as generous as the Mandatory Minimum Plan. For cost projection purposes it is assumed that this Minimum plan is the Non-Group benefit and that current employer plans would not be affected.

There will be no change to existing group plans, which would then continue as they do at present. Likewise other existing coverages would not change. Thus, there would be minimal disruption to the current arrangements.

Cost Projections

Mandatory Public Drug Insurance with Private Replacement Coverage – Main Costs Components

*Public costs reach 13% of
taxable income by 2050.*

Pre-Funding

This model blends public costs that could be pre-funded, (seniors and special support plans, payable by the entire population), public costs that would operate on a pay-as-you-go basis and private plans that would continue to operate on an annual premium basis, without pre-funding. This limits the potential benefits of pre-funding to a public plan, but it is believed that private insurers will not be willing to underwrite the long-term risk of claims inflation and utilization that results from pre-funding approaches.

Mandatory Public Drug Insurance with Private Replacement Coverage – Total Costs vs. Funding

Because of the larger role of the private sector, the impact of pre-funding is not as important as in the mandatory public model.

Sustainability

This arrangement would be somewhat more sustainable than the current model through the inclusion of a pre-funding element.

Opportunity for Choice

This offers as much choice as the current arrangements.

Opportunity to Link to Behaviour

There is little opportunity to link coverage to behaviour, except through the public plans, in which case the considerations outlined in the Mandatory Public scenario apply.

Implementation

Implementation would be relatively easy, but the following two issues should be mentioned:

- A method would be required for plan sponsors to annually report to the government that a given individual was covered for prescription drugs during a certain number of months. The T4 could likely be used for this purpose.
- Employers (and their insurers) would not be able to deny mandatory coverage to employees, their spouses or children. Some private plans, especially smaller ones, may be subject to high claims fluctuations due to individuals they would decline in the current system. A similar situation exists with the public-private mix plan in Quebec.

Insurers have responded by introducing a pooling of large losses that applies to all drug contracts in the province. Such an arrangement could be set up in Alberta.

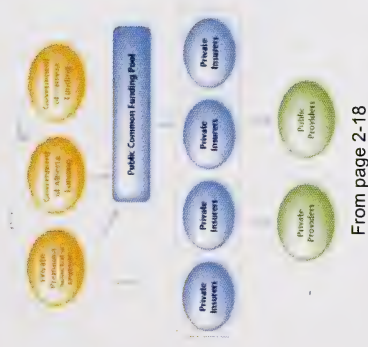

Conclusion

- This arrangement offers minimal disruption to the current arrangements.
- It provides universal coverage. Employers would have to provide at least the mandatory coverage to their pre-65 employees and their spouses and children.
- Employers could benefit from prices and fees negotiated by the government with dispensers, wholesalers and manufacturers.
- This model enables Alberta to exercise some degree of cost control by limiting funding and actively managing the minimum mandatory core benefit list.
- Private insurers could be allowed to offer supplemental or additional coverage to persons covered under the public plan, thus increasing choice.

Mandatory Private Drug Insurance with Public Premium Pooling

This insurance model is based on the following:

- The provincial government would provide funding either in a similar way to the province's current system or through a pre-funding model. Under a pre-funding model, the population would pay into a common pool of public funding at a rate expected to fund projected costs over a specified future period.
- In support of this system, individuals would need to select coverage from private carriers.
- The required insurance premiums for each private insurer would then be determined and distributed by the government based on the risk characteristics of each carrier's insured population.
- The types of plans offered would need to meet minimum standards of coverage defined and regulated by the government.

Under this arrangement, private carriers would not be allowed to revise their premium rates in an unregulated fashion. Instead, their pool of available premiums would be determined by the provincial government. Private carriers are then faced with delivering on their benefit commitments, providing for their own administrative expenses and achieving required profit margins within the constraints of available funding. To deal with these considerations, private carriers are expected to develop provider networks to negotiate compensation arrangements that fit within funding constraints. This would constitute a change in business focus for private carriers; one that they might not welcome.

Moreover, pharmacists might also be resistant to this approach, as there is no incentive for them to develop a network and agree to lower drug costs.

Cost Projections

This model does little to address the accelerated growth of drug costs, unless private carriers succeed in identifying and implementing measures that have this impact. However, their ability to do this is no greater under this model than it is under the current arrangement.

Mandatory Private Drug Insurance with
Public Premium Pooling – Main Costs Components

Because private insurers have limited opportunity for productivity gains in the drug area, costs are highest in this model.

Pre-Funding

Pre-funding is not expected to be acceptable to private carriers. However, the government could still adopt a pre-funding method for the determination of the public pool of funds that would be used to pay the private premiums. The total costs are projected to rise from about 4% of taxable income to about 20% by the year 2050. A pre-funded cost would represent about 9% of taxable income.

In this model, pre-funding is done within the public pool.

Sustainability

If the government can successfully limit available funding and private carriers can build profitable businesses on this basis, this would be a sustainable model.

Opportunity for Choice

There is extensive choice available to individual Albertans under this arrangement, limited potentially only by the extent of group insurance, under which the choice of carrier is made by the plan sponsor.

Opportunity to Link to Behaviour

There is limited opportunity to link behaviour.

Implementation

Implementation issues from the insurer's perspective have to do with ensuring adequate coverage for the uninsurable on terms that the private industry will accept. Issues also arise in connection with the insurer's acceptance of government control over how much premium revenue they will receive to honour their insurance commitments and meet stockholder profit expectations. Other than these points, this model closely resembles the current system for private carriers.

Conclusion

- This model has not been market-tested over time, so its true feasibility is not known.
- Success is a function of private carriers' abilities to run their businesses within revenues determined or constrained by government.
- Government would need to play an active oversight role.
- This model, when applied to prescription drugs, is more complex and expensive than the two other models discussed in this section.

Continuing Care

This document contains advice, proposals, recommendations, analyses or policy options developed for the Minister of Alberta Health and Wellness, and/or department of Alberta Health and Wellness.

Overview

This section is an actuarial projection and analysis of continuing care in the province of Alberta.

Analysis identified the following primary cost drivers of continuing care:

- Salaries;
- Capital costs; and
- Aging.

The current trend of salaries and capital costs is not excessive in comparison with general inflation and economic growth rates, but it is expected that population aging will create a material increase in costs.

The following graph displays the key sources of growth both through the year 2040 and over the entire projection period (based on the Mandatory Public scenario).

For continuing care, cost inflation drives costs, but unlike the other benefits, the significance of population aging is materially greater. This result shows how the disproportionately large costs of continuing care at later ages means that aging is relatively more important than in other benefits, where claim costs do not slope quite as steeply by age.

Pre-funding the increasing costs of continuing care was identified as the primary technique for minimizing the aging population effects.

No effective insurance policies were identified to directly reduce costs, although there may be scope to do so through operational efficiencies and increased use of capital. A detailed analysis of these approaches was outside the scope of this study.

Finally, a 45-year projection was required to fully account for the aging population and the pre-funding requirements. Although necessary, projections of this duration are highly sensitive to cost assumptions due to compounding effects. Premium and cost calculations would need to be continually revised to reflect underlying changes in the delivery of continuing care, as they impact short and long-term cost projections.

Continuing care is provided to home living based clients, facility based clients and supportive living based clients.

Home Living Based Clients

The main categories of clients are short-term, long-term and palliative. Services include assessment and coordination, nursing and therapy services, personal care, home making, social support and household operation.

Facility Based Clients

Long-term care facilities provide a range of health services to frail, disabled or chronically ill residents. Residents are based in facilities and are not able to live at home. Many services are offered on a 24-hour basis. Specialization has resulted in some facilities offering sub-acute care, respite care, palliative care and services to people with Alzheimer's or other dementias.

Long-term care facilities can either be owned and operated by the public sector (regional health authorities), not-for-profit or for profit organizations. There are approximately 208 long-term care facilities with 14,300 beds in Alberta.¹⁵

Supportive Living Based Clients

Supportive living is a conceptual and operational approach to provide continuing care services to seniors and adults with developmental or physical disabilities, while allowing them to live outside of an institutional setting. It enables the greatest amount of independent living possible within a series of medical, social and financial constraints.

Currently, there are approximately 20,000 supportive living spaces in Alberta in buildings owned and operated by public management bodies, as well as private and non-profit housing operators. Spaces are available in:

- Lodges;
- Enhanced lodges;
- Group homes;
- Assisted living; designated assisted living, adult family living and family care homes.¹⁶

Baseline Projection

Baseline projections are based on Scenario 2 of the Alberta Health and Wellness Regional Continuing Care Model (RCCM).¹⁷ This scenario assumes a “medium-shift” from facility-based services to community-based services until 2050.

Subsequently, the RCCM cost projections were revised in the following ways:

- Alberta Finance’s medium population projection was revised to reflect anticipated improvements in mortality rates;
- Unit cost inflation was increased to 4% to reflect anticipated trends;
- Percentage of total funding allocated for capital expenditures was increased to recognize obsolescence,¹⁸ and
- Expected costs from implementation of the “What We Heard & Draft Recommendations” produced by the Task Force on Continuing Care, were incorporated into the cost projections.¹⁹

As in the RCCM model, it is assumed that resident accommodation charges cover related costs, and that this policy will continue (note that accommodation charges and expenses are excluded from the current RCCM model).

The baseline projection can be broken down into three phases: 2005 to 2015; 2016 to 2040 and after 2040.

2005-2015

Costs will remain largely level, or may slightly decline, in proportion to provincial personal taxable income. There is no question that costs will be rising, but less so than economic growth and personal income. A moderate increase in use of supportive living is offsetting some of the cost increases associated with improving care. The effect of these additional expenses is to increase the level funding contribution by 0.1% of taxable income (assuming contributions by the whole population).

2016-2040

A significant shift occurs during this period as the working population’s proportion of total population declines, while there is a steady increase in demand for continuing care. This aging effect is compounded by the capital costs associated with high demand for long-term care facilities.

Taken together, the proportion of personal income needed to support continuing care will double during this period.

After 2040

Although the costs of providing continuing care are still rising, this is offset by a reduction in the need for capital expenditure. Essentially, there is no need to build additional long-term care facilities and this reduces cost.

Alternative Payer Approaches

Two different approaches were modelled to reflect different policies for collecting continuing care payments:

- *Universal premium base* – This model assumes that the entire working population is required to fund continuing care until they go into a continuing care program (i.e., premiums are collected until claims begin). This approach spreads the burden across the widest number of people, reducing the cost for those contributing.
- *Limited premium base* – This model assumes that continuing care payments are only collected from the population between the ages of 30 and 75. These ages were selected because:

Some jurisdictions do not require these types of premiums from younger people entering the workforce on the assumption that they need assistance when they are “starting out”; and

If premium payments continue beyond age 75 until someone enters continuing care, there will be a marginal incentive to enter continuing care earlier. Two methods can be used to avoid this problem:

Do not stop premiums when a beneficiary enters a long-term care facility; and

Discontinue premiums once the Index of Independence in Activities of Daily Living attains a given level (e.g., “D”).

This applies no matter if the beneficiary receives home based or facility based services.

Population Sensitivity

With population aging as a key driver of rising continuing care costs, changes to the population projections have a significant impact.

For example, the projected annual cost of continuing care against total provincial taxable income is 3.5% when the base (or medium) Alberta Finance population projection is used. When the high population projection is used, assuming a higher birth rate and net immigration rate of working age population, the cost to taxable income ratio falls to 2.8%. Should population growth fall short of the medium population projection and have an older average age, the cost to taxable income ratio increases to 4.2%.

Projected 2050 costs range from 2.8% of taxable income (high population scenario) to 4.2% of taxable income (low population scenario)

Similarly, continuing care costs as a proportion of provincial revenue are favourably impacted by higher population growth.

Consequently, for continuing care, increases in net immigration and population growth can improve sustainability. However, the cost to taxable income ratio will still double over a 35-year period with the most favourable demographic projection.

Need for Mandatory Insurance

Due to the anti-selection phenomenon²⁰, for an insurance model to replace the current pay-as-you-go approach, coverage will need to be mandatory and universal. Otherwise, there would be a significant risk that large portions of the population will be uninsured at the time they require continuing care, and will therefore require some other form of social assistance. Essentially, these individuals will make no payments and then rely on the government to support them. Mandatory health insurance ensures everyone pays for services they could potentially use.

Mandatory Public Health Insurance

The introduction of mandatory public health insurance for continuing care changes the current funding mechanism without materially impacting the provision or management of delivering services.

Insofar as premiums are income based, it is assumed that they are collected through taxes.

From page 2-12

Cost Projections

Given little change to operations and the underlying cost structure, this insurance model assumes no impact on:

- Utilization rates;
- The split between residents using public and private facilities; and
- Inter-provincial migration patterns.

Consequently, there is no material impact on the cost projections with the mandatory public health insurance model.

Projected Annual Cost – Mandatory Public

Pre-Funding

Early collection of premiums that exceed costs will create a reserve to fund future continuing care costs. The investment income for the reserve helps reduce the long-term burden of continuing care. As discussed previously, there is limited opportunity in continuing care to materially reduce costs beyond what is currently planned (with the possible exception of some capital investment to increase productivity). To the extent that this is true, pre-funding is the only viable mechanism to reduce growth in continuing care and limit the peak costs in terms of taxable income or provincial revenue.

The level per cent of taxable income basis for expressing the funding charge is a logical basis to use, because taxable income is a readily recognized index that ensures a reasonable match between required funding and ability to pay. It does however have one deficiency – a percentage is not necessarily easy to interpret in dollar terms. Thus Alberta Health and Wellness also requested that the flat dollar funding contribution per capita that would pre-fund all projected costs to 2050 be determined. This flat dollar charge gives a useful estimate of the average impact of funding on all Albertans, ignoring differences in income. As such, it is essentially an average across all income levels and is provided as a rough measure rather than a recommended approach. This flat dollar amount is \$779 per capita. In determining this amount:

- The flat amount was indexed at 4% per year; and
- Albertans aged less than 16 were excluded from the calculation.

This compares with the level percentage of taxable income specified later in this section (2.4%).

The following graph compares the flat charge with the level per cent charge, using 2006 taxable income, separately for males and females.

Where the entire population makes continuing care insurance premium payments, the pre-funding rate would be 2.4% of personal income. This is lower than the peak premium payable of 3.4% in 2040 that would otherwise occur without pre-funding.

Should only the population between the ages of 30 and 75 make contributions, a level premium rate of 2.9% would offset the increase of 1.8% to 4.2% during the 2010 to 2040 period.

In the event that the level premium rates are not viable, the reserve could be funded from a combination of sources. In addition to individuals, employers could be

required to make matching contributions (although this would raise their effective tax rate). Alternatively, the Government of Alberta could contribute to the reserve through general revenue or by creation of an endowment from natural resource revenue.

Finally, pre-funding could be done on a partial basis, by selecting a rate between the level rate and the current cost. This would mitigate the impact of cost increases, while reducing the effect of a sudden increase in collected pre-funding premiums (or taxes). The specific level of pre-funding critically influences the magnitude of these effects.

Level funding improves sustainability of the plan but the impact is less pronounced than in other benefit groupings with faster rising cost by age.

Projected Annual Cost – Level Funding – Mandatory Public

Sustainability

Public mandatory insurance has no underlying impact on costs, and can contribute to sustainability through pre-funding.

Opportunity for Choice

This model does not impact the current level of choice for continuing care, which currently includes a mix of public and private (non-profit and for profit) providers.

Note that accommodation fees are excluded from this model, and would need to be purchased by those receiving care, as they are today.

Opportunity to Link to Behaviour

The mandatory public scenario offers little scope to directly link premiums to responsible lifestyle decisions.

Conclusions

- With little disruption to the current continuing care provider network, this type of plan would be relatively straightforward to introduce.
- Its primary benefit is to enhance sustainability by providing a level funding contribution percentage.

Mandatory Public Health Insurance with Private Supplemental Coverage

This model assumes that there is a core public health insurance plan similar to the mandatory public health insurance model. However, private health insurance is available for those that would like to have coverage for additional or higher quality benefits, such as enhanced levels of continuing care.

From page 2-14

Although supplemental private health insurance plans are currently available, sales are minimal. Increased plan use may require tax or other financial incentives to increase public demand, or offset some portion of the risk that insurers pass on to consumers, by limiting the total monthly payouts and de-indexing from inflation. Health savings accounts would also complement, or possibly replace this type of insurance, with tax advantaged savings available to purchase continuing care services, beyond those provided by the core mandatory public health insurance plan.

Cost Projections

The cost projection for mandatory public health insurance is not expected to increase as underlying cost dynamics remain unchanged. There will be additional costs, however, to the extent that private services are purchased to upgrade the level of continuing care. These will be largely determined by supply and demand. Purchasing private services has been conservatively estimated to increase by 10% based on an average of experience in other countries.²¹

Projected Annual Cost – Mandatory Public with Private Supplemental

Note: Public contribution is assumed to be paid by the entire population.

Sustainability

The public mandatory health insurance element of this model can use pre-funding to enhance sustainability. To the extent that additional private coverage is optional and not medically necessary, the open market forces that determine total expenditure are not necessarily material to the sustainability question.

The conceptual model has little impact on the pattern of projected future claims.

Opportunity for Choice

This model marginally increases the level of choice for those able to afford it. Given the relatively low uptake in insurance sales today for such coverage, it is unclear whether the level of choice will materially increase without some government incentives.

Opportunity to Link to Behaviour

The mandatory public component in this model offers little scope to directly link premiums to responsible lifestyle decisions.

Similarly, the supplemental private health insurance component is unlikely to have a material effect on behaviour.²²

Conclusions

- In comparison to public mandatory health insurance, this conceptual model provides marginally increased choice for continuing care insurance coverage by providing private supplements for a marginally higher total cost (with no change in public expenditure).

Mandatory Private Health Insurance with Public Premium Pooling

With a public body collecting mandatory premiums and then paying individual premiums to insurers based on the risk they carry, this conceptual model blends many of the attributes of private and public health insurance. As noted previously, the precise design of the policies will have a significant impact on actual pricing and benefits offered to the population.

Cost Projections

Introducing private insurers changes the cost projection dynamics. The major effects include:

- Additional expenses for marketing, the cost of capital, and the need for a return on investment; and;
- Possible productivity gains linked to increased use of capital and improved operational processes.

For any supplemental insurance beyond the core mandatory health insurance policy, cost dynamics will remain the same as the mandatory public health insurance with supplemental private coverage.

An average increase in productivity of 1% per year during the first 15 years is assumed. This rate closes much of the productivity gap between health care sector and the general economy by 2020, but is based on general statistical trends. Validation that productivity improvements are practical through a review of potential capital use and operational improvements is recommended prior to any final decision on funding.

Although mid-term costs are higher (until 2015), this model results in a slightly lower level premium as a percentage of taxable income (2.1% with mandatory private health insurance with public premium pooling versus 2.4% with public mandatory health insurance). This reflects the long term accumulation of capital to improve productivity and the ongoing operational changes associated with this modelling approach.

**Projected Annual Cost – Mandatory Private with Public Pooling
– Level Funding**

Sustainability

This model is marginally more sustainable than the others, as it has lower peak and level premiums, but is critically dependent on private insurers being the catalyst for increased productivity and lower costs. There is a risk that this will not occur, and sustainability would be compromised.

To the extent that additional private coverage is optional and not medically necessary, the open market forces that determine total expenditure are not necessarily material to the sustainability question.

Opportunity for Choice

This model increases the level of choice to the extent that insurers are able to offer

insurance coverage for continuing care services beyond the minimum coverage required. There is limited international experience for this approach for funding continuing care, so this hypothesis is untested for these types of health services.

Opportunity to Link to Behaviour

The mandatory private health insurance component offers little scope to directly link premiums to responsible lifestyle decisions as the premiums are pooled.

The supplemental coverage element of the model means it is unlikely that there will be insurance mechanisms to encourage healthy lifestyles for continuing care.

Implementation

To achieve its potential, this model requires private delivery of services. So it would involve selling or leasing publicly-owned long-term care facilities to the private sector. Prior discussions would be required with the insurance industry to ensure that a sufficient number of insurers would enter this market.

Conclusions

- In comparison to the public mandatory health insurance plan, this conceptual model provides the potential for increased choice and a marginal reduction in the base cost of continuing care. However, there is a risk that the productivity gains

anticipated by privatization are not realized, and that the cost does not decrease, but increases.

- To the extent that private providers of continuing care (in addition to the current private accommodation) can be introduced successfully into the continuing care system, the impact of cost reduction from introducing insurance would be lessened.

Mandatory Private Health Insurance

The long term and high level of inflation risk made this approach untenable insofar as private insurers are unlikely to offer coverage that is affordable to the Alberta population.

From page 2-21

Private coverage would require risk based premiums and the related underwriting expenses. Some people would not qualify for coverage due to health conditions. Mechanisms exist to pool such risks but this model does not offer any advantage compared to the mandatory private health insurance with public premium pooling model.

Optional Private Health Insurance

This insurance model was not assessed in detail. No viable implementation approach was identified that could meet the fundamental objectives of Alberta Health and Wellness. This approach would leave large portions of the population requiring continuing care without insurance coverage, which is an unacceptable outcome.

From page 2-22

Continuing Care Appendix

This document contains advice, proposals, recommendations, analyses or policy options developed for the Minister of Alberta Health and Wellness, and/or department of Alberta Health and Wellness.

Overview

This appendix complements the Continuing Care section in the *Health Benefit Design Options* for Alberta Health & Wellness Report, March 29, 2006. It models the potential impact on costs and insurance premiums should the fee for a semi-private room in a continuing care facility be included as a benefit under the insurance models. For the purpose of this appendix, this additional cost will be referred to as “Accommodation Fees”.

With the exception of assumptions and comments relating to Accommodation Fees, assumptions and comments found in the Continuing Care section remain accurate. This appendix focuses only on elements directly related to Accommodation Fees.

Building on the analysis found in the Continuing Care section of the main report, we explored the cost impact of adding the Accommodation Fees – assumed to be \$42 per day per client in 2006 – to various conceptual insurance models. The incremental \$42 unit cost reflects the current cost of a semi-private room, and is assumed to increase annually based on the inflation rate used in the Continuing Care section. Private room clients would pay an additional \$6 above the \$42 Accommodation Fee.

Mandatory Public Health Insurance

Cost Projections

Pre-funding

The flat dollar amount that would pre-fund all projected costs to 2050 is \$870 per capita (this compares to \$779 per capita without Accommodation Fees). Albertans aged less than 16 were excluded from these calculations.

The corresponding level percentage of taxable income is 2.7% (compared to 2.4% without Accommodation Fees).

This graph compares the flat funding dollar amount with the level per cent charge using 2006 taxable income for males and females.

The term flat funding refers to an amount that is, during a given year, constant across all levels of taxable income. However, this flat amount is assumed to increase at 4% per annum.

Should only the population between the ages of 30 and 75 make contributions, a 3.2% level premium rate would be required to fund continuing care costs (compared to 2.9% without Accommodation Fees).

Mandatory Public Health Insurance with Private Supplemental Coverage

Cost Projections

Note: Public contribution assumes the entire population pays the annual premium.

Level funding = 2.7%

Mandatory Private Health Insurance with Public Premium Pooling

Projected Annual Cost – Mandatory Private with Public Pooling – Level Funding

Level funding = 2.5%

Implications of Including Accommodation Fees

Although approximately 60% of clients currently have a private room, we assumed that only the cost of semi-private room would be covered by the insurance program. Note that having the insurance program cover the cost of a private room would increase demand for private rooms but this demand could obviously not be met by existing facilities.

Given the almost universal receipt of Old Age Pension by Albertans aged 65 and over, having the insurance program cover 100% of Accommodation Fees seems to leave clients with a significant amount of "pocket money".

Since the \$42 would be payable irrespective of whether clients elect to stay in publicly or privately owned facilities, this benefit would not change the expected mix of private / public clients.

The semi-private benefit would create a slight incentive for clients to use facility-based care, rather than aging in place. However, since eligibility criteria is based on medical conditions, no material increase in usage is expected (nor was such an increase included in the model).

Non-Emergency Health

This document contains advice, proposals, recommendations, analyses or policy options developed for the Minister of Alberta Health and Wellness, and/or department of Alberta Health and Wellness.

Overview

At present, Alberta Health and Wellness does not offer non-emergency services as a separate category of services. Instead, both emergency and non-emergency services are offered without any differentiation. As a result, it was necessary to adopt a protocol to identify those services that would be considered non-emergency for purposes of the analysis.

It was decided that the triage score assigned upon registration at the emergency room should be the basis for defining services as emergency or non-emergency. These scores are based on the Canadian Emergency Department Triage and Acuity Scale, a nationally recognized scale used in all provinces for the purpose of ensuring that the most urgent cases presenting themselves to emergency are treated first. The scale consists of the following five levels:

- *Level I – Resuscitation* – Conditions that are threats to life or limb (or imminent risk of deterioration) requiring immediate aggressive interventions.
- *Level II – Emergent* – Conditions that are a potential threat to life, limb or function, requiring rapid medical intervention or delegated acts.
- *Level III – Urgent* – Conditions that could potentially progress to a serious problem requiring emergency intervention. May be associated with

significant discomfort or affecting ability to function at work or activities of daily living.

- *Level IV – Less Urgent (semi-urgent)* – Conditions related to patient age, distress or potential for deterioration or complications; would benefit from intervention or reassurance within one to two hours.
- *Level V – Non Urgent* – Conditions that may be acute but non-urgent as well as conditions which may be a part of a chronic problem with or without evidence of deterioration. The investigation or interventions for some of these illnesses or injuries could be delayed or even referred to other areas of the hospital or health care system.

After evaluation of the five levels defined above, it was decided for purposes of this analysis that triage scores of one or two would be regarded as emergency and therefore would fall beyond the scope of this analysis.

The remaining triage scores would then be classified as non-emergency and fall within scope. This provides analysis of the maximum impact of insurance, recognizing that a more limited group of services could subsequently be assessed.

In summary then, non-emergency health consists of the following types of services:

- Emergency room visits with a triage score of three or more. Visits with lower triage scores are excluded from the definition of “non-emergency”.

- Hospitalizations resulting from the emergency room visits referred to above.
- Other hospitalizations, that is, hospitalizations that do not result from emergency room treatment.
- Treatment rendered at hospital ambulatory care centres.
- Treatment provided at a general practitioner's or a specialist's office.
- Physician's services provided at a hospital ambulatory centre following emergency room treatment.
- Physician's services rendered in connection with in-patient care or in a long-term care facility.
- Physicians' fees in connection with diagnostic or therapeutic services.
- Community laboratory and other diagnostic fees.

At present non-emergency health services are all provided publicly through Alberta Health and Wellness and the regional health authorities. Recent growth rates in costs for these services have been quite high in Alberta, both in absolute terms and in comparison to other provinces. In the 2004/05 fiscal year, more than \$4.0 billion was spent in providing the above services to Albertans.²³ Funding for publicly provided services is currently available from a variety of sources, on a pay-as-you-go basis:

- Federal government transfers under the *Canada Health Act*.
- Direct contributions from Albertans, which are referred to as "premiums" although they are not developed according to insurance principles.
- General government revenues.

Neither the current plan design nor the current funding arrangements provide any incentive or mechanism to reduce demands on the system.

Summary of Findings

Baseline Analysis

The baseline analysis projects costs through the year 2050 assuming that no changes are made in plan design, funding or the delivery system. Thus recent patterns of growth are projected forward unadjusted through 2050.

Costs

Claim projection factors

- a. Claim projection factors were developed and applied to per capita claim rates developed from data provided by Alberta Health and Wellness. The development of the factors was based on data published by The Canadian Institute for Health Information (CIHI). The analysis uses per capita costs published in a report entitled "Provincial and Territorial Government Health Expenditures By

Age Group, Sex and Major Category: Recent and Future Growth Rates".²⁴

- b. The figures in the report are in 1997 dollars, using the Implicit Price Index (IPI) as a deflator.
- c. The report displays growth rates for all ages and both genders combined, both by province and for the whole of Canada. It also shows costs by age and sex for the whole of Canada.
- d. To develop costs by age and sex for Alberta, the costs by age group and sex in (c) above were increased by the appropriate IPI and adjusted by the difference between Alberta costs and those for the whole of Canada. Thus it is assumed that the following two elements do not vary by age or sex:
 - IPI; and
 - Alberta-specific differences.
- e. Benefit groupings shown were:
 - Hospitals;
 - Other institutions;
 - Physicians; and
 - Other professionals.

- f. The resulting projection factors by age and sex are shown in the table below.
- g. The projections were based on (e)(i) above for each of hospital accommodation, emergency room charges and ambulatory charges and on (e)(iii) above for all other elements of non-emergency medical care, (that is, for physicians' costs and for laboratory and other diagnostic charges).

Per Capita Claims Projection Factors

Age Group	Males – Hospital	Females – Hospital	Males – Other Expenses	Females – Other Expenses
Less than 1	7.8%	8.1%	7.5%	7.2%
1-4	6.4%	6.9%	6.9%	5.7%
5-14	5.3%	5.6%	6.3%	6.3%
15-44	6.5%	6.3%	7.6%	7.1%
45-64	6.8%	6.2%	8.5%	7.7%
65-74	6.7%	7.0%	8.7%	8.6%
75-84	7.1%	7.4%	9.0%	9.0%
85 or more	7.9%	7.9%	9.4%	8.8%

Total

Total projected costs from the model were \$5.1 billion in 2006. By the end of the projection period, cost inflation and population growth had combined to increase this amount to \$245.8 billion. As a per cent of projected taxable income, costs grew from 5.5% in 2006 to 37% in 2050.

*The cumulative growth rate
leads to extremely high costs
that would be unaffordable for
Alberta by 2050.*

If the provincial government chose to immediately implement a “pre-funding” approach to provide for anticipated costs through the year 2050, the equivalent level per cent of taxable income required to cover baseline costs is 15.95%. For some years thereafter, this financing cost would exceed the current annual costs, thereby generating surplus. The surplus would be invested in a dedicated trust fund to ensure that it was not spent for other purposes; it would be required to pay later year costs, which would be

expected to exceed the available financing. The expectation of investment credits reduces the degree of financing required by Albertans.

The modelling assumptions, combined with the assumption that taxable incomes will grow by 4% per year for those aged less than 65 and by 2% per year for those age 65 or more, lead to a “cross-over point” in 2031, where costs exceed available current year financing.

By Age

Costs per capita displayed a fairly consistent pattern. While costs for the age category zero-to-four were quite high, they declined for the next two or three age categories and began to rise thereafter, peaking at ages 90 and above. This led to a characteristic U-shaped graph of costs by age category.

Although per capita costs rose steeply by age, the distribution of covered population by age is such that older ages do not represent the bulk of the costs. Nevertheless, aging of the population is an additional cost driver as more of the population lives longer.

By Gender

Outside of the child-bearing years, per capita costs for females tended to be lower than for males. This pattern is consistent with other studies and was therefore not unexpected.

Non-Emergency Health – 2006 Per Capita Costs By Age and Gender

In 2006, nearly one-third of total costs arise from those aged 65 or more. Noting the rapid increase in per capita costs by age and the expectation of an aging population, it is clear pre-funding is potentially very helpful in providing for the expected costs of public insurance.

Mandatory Public Health Insurance

The baseline analysis summarized above is essentially an extrapolation, using current per capita costs and recent inflationary trends projected far into the future. This means that it produces unreasonable results as the end of the projection period is approached.

From page 2-12

For example, by the year 2050, projected costs for this benefit grouping reach 37% of projected taxable income. Such disproportionate expense on one segment of health care alone is certainly unsustainable; therefore, the baseline scenario should not be used as the basis for any detailed analysis.

In the mandatory public health insurance scenario, the government is expected to provide a single, centrally administered source of insurance coverage. The required financing would be determined by:

- Using appropriate insurance principles to project costs; and
- Assessing required premium rates expected to be sufficient to meet costs over periods to be defined by reference to desired public policy outcomes.

For illustrative purposes, the projected financing has been expressed as a level per cent of taxable income sufficient to meet projected costs through the year 2050. By expressing it compared to taxable income, it is easy to assess the true affordability of the model.

The level per cent of taxable income basis for expressing the funding charge is a logical basis to use because taxable income is a readily recognized index that ensures a reasonable match between required funding and ability to pay. It does, however, have one deficiency – a percentage is not necessarily easy to interpret in dollar terms. Thus, Alberta Health and Wellness also requested that the flat dollar funding contribution per capita be determined that would pre-fund all projected costs to 2050. This flat dollar charge gives a useful estimate of the average impact of funding on all Albertans, ignoring differences in income. As such, it is essentially an average across all income levels and is provided as a rough measure, rather than a recommended approach.

This flat dollar amount is \$3,965 per capita. In determining the flat amount:

- The flat amount was indexed at 4% per year; and
- Albertans aged less than 16 were excluded from the calculation.

This compares with the level percentage of taxable income specified later in this section (12.16%).

The following graph compares the flat charge with the level per cent charge, using 2006 taxable income, separately for males and females.

To calculate the required level financing percentage of taxable income, no taxable income was excluded. That is, neither minimum nor maximum were implemented. Adoption of such minimums and maximums, although it would be clearly desirable in social terms, would increase the required financing percentage.

In modelling mandatory public health insurance, the growth factor applied to per capita claim rates after the year 2015 was reduced to 6% for all ages except those age/sex cells for which it was already less than 6%. In this context it is important to bear in mind the fact that Alberta has experienced higher than average growth in its per capita costs for hospitalization and physician costs compared to other provinces, (2.1% more for

hospitalizations and 3% more for physicians' costs).²⁵ It would be prudent to set an affordable rate of future growth in per capita costs and identify changes in practice that could potentially assist in achieving this target. Relevant considerations include:

- Community-based care is less expensive than institution-based care. (Note that Alberta Health and Wellness has already implemented changes in its long-term care delivery strategy to encourage "aging in place", fundamentally a strategy for promoting community-based care, when it is appropriate.)
- At present, there is little emphasis on preventive measures; instead the system is oriented to treatment of acute conditions.
- Currently, outcomes measurement and productivity measurement are rarely used as a tool for effective delivery of health care services.

There arises a natural question – what specific changes could be implemented that might reduce future growth in costs? Unlike prescription drug benefits, there has been relatively little effort expended either by governments or by private insurers in identifying such activities in connection with non-emergency health. Thus the following are presented as suggestions that may stimulate discussion and provide building blocks to improve processes rather than final recommendations:

- Use outcomes measurement to identify the providers and processes (if relevant) that deliver the most favourable health outcomes. Use this information as deemed appropriate, for example:
 - Reduce the province's exposure to processes or providers that deliver sub-optimal results;
 - Change compensation structure for providers to reduce the economic incentive to conduct multiple tests and see many patients; or
 - Use outcomes measurement as the basis for focused training meant to ensure that better processes are widely adopted.
- Be alert to opportunities to meet demand growth through investment of capital instead of through adding more people to the delivery system.
- Develop plan designs that emphasize preventive care. Continue to emphasize the value of healthy lifestyles, both as a quality of life issue and as a means to reduce demands on the medical system.
- Identify initiatives taken in connection with other benefit groups that also have the potential to reduce non-emergency costs. For example, it has been estimated that 17% of all drug-related hospitalizations arise from improper prescribing. By adopting tools and promoting education aimed at reducing improper prescriptions, Alberta Health and Wellness would improve not only prescription

drug experience, but also hospitalization experience.

- Noting that Alberta's rates of cost growth have exceeded those of other provinces during the last ten years, study processes and history of other provinces to identify practices that might reduce Alberta's growth to similar levels to those found in other provinces.

The successful search for initiatives that directly affect growth in costs would offer the potential to achieve a future growth rate of 6% or perhaps even lower.

The ability to achieve a 6% trend would have a significant impact on costs:

- Costs would rise to \$146 billion by 2050, instead of the \$245 billion under the baseline scenario.

The final projected costs are 22% of projected taxable income of the entire population in 2050.

- The equivalent level funding per cent of taxable income is 12.16%, a reduction of nearly 25% from the baseline scenario.

Note though that the 6% target, though difficult to achieve, still represents a growth rate roughly double the CPI. Thus it would still impose significant stresses on the future provincial economy.

The impact of lower inflation can be seen in the reduction of the level funding percentage by nearly 25% compared to the baseline scenario. However, growth in actual costs is still significant over the projection period. Inability to limit inflation would have serious consequences.

Non-Emergency Health – Baseline Costs and Mandatory Public Health Insurance Cost Comparison

Non-Emergency Health – Impact of Federal Transfers on Mandatory Public Scenario

Federal transfers are significant, but impact is projected to decline.

Key Cost Drivers

Key cost drivers tend to be the same for any benefit grouping and in any scenario. Essentially future costs are expected to grow because of the combined impact of the following factors:

- Population growth;
- Aging population;
- New technology;
- Rising demand; and
- Provider expectations.

Since providers will expect, over a period of years, to see their incomes rise at a rate that exceeds consumer price inflation, provider expectations represent a minimum level for projections. Thus, the minimum expected increase is in excess of CPI. The other four factors listed above will normally tend to drive health costs higher yet,

although net population growth also enhances the population's ability to fund health care costs.

An important element of cost in this scenario is the provincial government's ability to control costs by limiting available funding. The weakness in this strategy is that it fails to address issues like demand growth. As a result, any cost control initiative based in limiting funding would need to be coupled with appropriate measures to ensure that the population continues to be satisfied with the quality of the care that it receives.

The following graph displays the key sources of growth both through the year 2040 and over the entire projection period.

The graph above shows that over the entire projection period, cost inflation is the primary cost driver. Population growth and aging also contribute to increased costs, but to a lesser degree. Note as well that population growth leads to economic growth. This can potentially offset the resulting increase in medical costs.

Sustainability

This approach offers hope for sustainability if it is combined with pre-funding. In this scenario, it is important to adopt appropriate measures to limit costs without damaging quality. As a result, using waiting lists as a tool for cost reduction is not an option.

Opportunity for Choice

Under this arrangement, health care funding is provided through a centrally administered system. As is the case under the current system, there is freedom to select certain health care providers, but there is no choice of insurance provider available.

Opportunity to Link Behaviour

The mandatory public health insurance scenario offers little opportunity to link available health care to behaviour, unless the government wishes to consider brand new policy initiatives such as varying the coverage available by health status, e.g., obesity or smoking status, or contemplating the use of cost sharing or other user fees in reimbursing certain types of services. It would be prudent to assess any such initiatives in advance to understand their potential impact on federal transfers under the *Canada Health Act*.

Sensitivity Testing

The following additional scenarios have been tested:

- Ultimate inflation rate 1% higher, at 7%;

- Ultimate inflation rate 1% lower, at 5%;
- High population scenario;
- Low population scenario; and
- Salary indexation of 1% less for under age 65 and 0.5% less for age 65 or more.

The first two scenarios test the possibility that utilization will vary from that assumed in the base mandatory public health insurance projections. The next two examine the capacity of the population to tolerate the expected level of increases under different assumptions as to net immigration and births. The final scenario tests the impact on available funding in the absence of strong economic growth. It will be seen that low economic growth imposes the greatest burden on the population, with costs projected to exceed 32% of taxable income by the year 2050, followed by high inflation, under which costs approach 30% of taxable income by the year 2050. The other scenarios are relatively benign in their impact on the province's ability to absorb the projected increases. In terms of level financing, low economic growth and high inflation each add from 2% to 2.5% to the required financing percentage; the others have a more modest impact or even a favourable impact.

Non-Emergency Health – Sensitivity Comparison

The inability to maintain high economic growth or to limit cost inflation undermines sustainability.

Conclusions

- Net immigration into the province potentially increases funding capacity.
- Focus must be on effective, prompt service delivery if funding is used as a tool to limit cost growth, because demand is expected to increase.
- Economic growth and inflation have the largest single impact on costs, which suggests that research is needed into means of limiting growth in demand and maintaining or increasing the healthy growth rates that have characterized the provincial economy in recent years.
- Level funding is not a panacea – by the year 2050 the projected level funding surplus has reduced to zero, but costs continue to rise faster than the economy.

Mandatory Public Health Insurance with Private Supplemental Coverage

Preliminary testing was conducted of a model that sorted non-emergency health services into two segments – one to be publicly financed and the other to be privately financed. The second segment could either be optional or mandatory.

From page 2-14

Public Services

Public services included:

- Emergency room treatment with triage scores of 3 or more and all resulting hospitalizations;
- Physicians' services delivered in hospital, except ambulatory; and
- Diagnostic and therapeutic services, including community lab.

Private Services

Private services included:

- Ambulatory services; and
- Physicians' services delivered in the ambulatory centre or outside of a hospital setting.

Key Cost Drivers

The following factors drive cost:

- Population growth;
- Aging population;
- New technology;
- Rising demand; and
- Provider expectations.

Sustainability

Since public acceptance of a design that potentially varies funding sources between public and private for different elements of a single course of treatment is unlikely, this model is not believed to be sustainable.

Consideration was also given to a model in which specified treatments would be removed from the public domain and offered privately. One possible example was hip replacement, in which potential recipients who had previously bought the coverage would be allowed to bypass waiting lists or access a more extensive type of replacement. However, this model is also expected to be unsustainable, as the potential private market would be much too small to interest a prospective insurer in the market potential or to convince the insurer that there would be a large enough spread of risk to enable profitable insurance pricing.

Opportunity for Choice

In this model, there is very little opportunity for choice for publicly financed benefits, with significant opportunity for choice among privately financed benefits if the private insurance market believes there is a viable market.

Opportunity to Link Behaviour

This model offers only limited opportunity to link to behaviour.

Sensitivity Testing

No sensitivity testing was conducted.

Conclusions

This model was judged unsustainable for non-emergency health services and as a result no additional testing was conducted.

Mandatory Private Health Insurance with Public Premium Pooling

This insurance model is based on the following:

- The provincial government would provide funding, either in a similar way to the province's current system, or through a pre-funding model, where the population would pay into a common pool of public funding at a rate expected to fund projected costs over a specified future period.
- The required insurance premiums for each private insurer would then be determined and distributed by the government based on the risk characteristics of each carrier's insured population and the mandatory coverage level.
- In support of this system, individuals would need to select coverage from private carriers.
- The types of plans offered would need to meet minimum standards of coverage defined and regulated by the government.

Under this arrangement, private carriers would not be allowed to revise their premium rates in an unregulated fashion. Instead, their pool of available premiums would be determined by the provincial government. Private carriers are then faced with delivering on their benefit commitments, providing for their own administrative expenses and achieving required profit margins within the constraints of available funding. To deal with these considerations, private carriers are expected to develop provider networks to negotiate compensation arrangements that fit within funding constraints. This would constitute a change in their business focus, one that they may not welcome.

Important modelling assumptions for this scenario include initial cost increases resulting both from administrative costs and from private profit margins, but compounding cost savings offset these increases in the future. This leads to first year projected costs of 104% of those of the public model. These costs would potentially fall to 92% of public model costs by the year 2020, at which level they were assumed to remain. With these assumptions, annual costs rise from \$5.4 billion in 2006 to \$135 billion in 2050. Expressed as a per cent of taxable income, the increase is still considerable – rising from 5.8% in 2006 to 20.2% in 2050. The equivalent level funding per cent is 11.3% of taxable income.

Productivity gains are central to financing affordability.

Non-Emergency Health – Mandatory Private Health Insurance Compared with Baseline and Mandatory Public Health Insurance

Key Cost Drivers

The following factors drive cost:

- Population growth;
- Aging population;
- New technology;
- Rising demand; and
- Provider expectations, as negotiated with the private carriers.

Private carriers include a profit margin in their pricing, which is a factor that has no counterpart in public financing models. In addition, it may well be that moving from a single, centrally administered plan to one with de-centralized administration offered by multiple sources will tend to drive administrative costs up. There is potential to offset this if private carriers succeed in negotiating provider arrangements that offer permanent, compounding savings compared to other models. In summary, this model appears to offer the likelihood of higher initial costs with possible future savings.

Sustainability

If government can limit available funding and private carriers can successfully build profitable, efficient delivery networks that achieve productivity gains, this model has the potential to be sustainable.

Opportunity for Choice

Consumers would have freedom to choose the plan and the insurer that they wished, except to the extent that selection of insurers was made by an employer sponsor of a group insurance plan, so this model offers maximum scope for individual choice.

Opportunity to Link Behaviour

The opportunity to link to behaviour in this scenario is a function of the plan design mandated by the government.

Sensitivity Testing

The relative impact of changes in inflation, population and salary indexation would be very similar in this scenario to those modelled under the mandatory public health insurance scenario.

Conclusions

- It is suggested that Alberta Health and Wellness assess the impact of such an approach to non-emergency care delivery on federal transfers under the *Canada Health Act*.

- Extremely large accounting liabilities would be imposed upon private employers if all non-emergency benefits were privately offered and mandatory.
- There would very likely be an immediate increase in costs, with the possibility of future reductions.
- Given the different business model required of private insurers to operate under this scenario, significant time would need to be devoted to working with the private industry to prepare for it.
- The private industry might resist this model, on the grounds that it would impose a large potential profitability risk without allowing them the latitude to price in accordance with their expected risk (because of government control over available financing).
- The long-term success of this approach would be determined by the government's ability to constrain private funding and private carriers to build a profitable business under this model, while achieving productivity gains with their provider base.
- Government would need to exercise a significant degree of oversight to ensure that plans met regulatory minimums and met appropriate quality standards.

Supplemental Health

This document contains advice, proposals, recommendations, analyses or policy options developed for the Minister of Alberta Health and Wellness, and/or department of Alberta Health and Wellness.

Overview

At present, supplemental health care is largely privately insured, although the Alberta health system offers limited coverage of certain supplemental health care services on a public basis. Private plans are essentially group insurance plans negotiated by employers or unions on behalf of their employees or members, although there is a small volume of individual policies. Since private carriers generally do not wish to accept the long-term risk of claims utilization and inflation, private plans are typically priced on an annual renewable term basis.

Public plans are currently funded on a pay-as-you-go basis under which costs are paid or incurred with little incentive to manage them.

The present system does not provide universal coverage for all Albertans. Specifically, there are individuals who do not qualify for the limited public coverage and are not covered for private benefits. These individuals would generally fall under the following groups:

- Self-employed and their dependents;
- Unemployed and their dependents; or
- Retired individuals without access to post-retirement insurance. (Some group plans offer post-retirement coverage, but recent changes in Canadian accounting requirements have created an incentive for employers to eliminate such offerings.)

Based on the extent of prescription drug coverage, it is likely that approximately 30% of Albertans of working age are not covered for supplemental health benefits.

Some of these individuals may have the means to buy individual coverage. However, individual coverage may not suffice. First, it generally requires the submission of evidence of insurability. Second, the scope of individual coverage may not match that of prevailing group insurance plans.

The specific benefits involved may be characterized as a typical group extended health care policy, without prescription drug coverage. As such, the benefit package modelled in this study consists of:

- Private duty nurses when ordered by a physician;
- Paramedical specialists (physiotherapists, chiropractors, acupuncturists, podiatrists, chiroprodists, naturopaths, homeopaths);
- Psychologists;
- Speech therapists;
- Registered massage therapists;
- Ophthalmologists and optometrists;
- Osteopaths;
- Dental accident coverage within ninety (90) days of an accident;
- Vision care (lenses, frames and eye examinations);

- Hearing aids;
- Mobility aids, prosthetic equipment, diagnostic laboratory tests, x-ray procedures and other medical supplies, including hospital-type bed, wheelchair and other such medical and mobility devices when medically necessary;
- Orthotic devices prescribed by podiatrists, chiropractors, chiropodists, or orthopaedic surgeons; and
- Orthopaedic shoes, up to one pair every 12 months (three pairs if under 19 years of age) prescribed by an orthopaedic surgeon.

In the private health insurance industry, such coverage is typically sold subject to deductibles and co-payments. Based on a forecast prepared by The Canadian Institute for Health Information, it is estimated that the cost of such coverage to Albertans in 2004 exceeded \$1.7 billion, including out-of-pocket expenses.²⁶ Recent renewal increases for coverage in the private health insurance industry exceed those applicable to non-emergency health. Many private carriers have moved to limit plan designs to contain this growth, thereby shifting costs to the claimant.

Summary of Findings

Baseline Analysis

As was the case with non-emergency health care, the baseline analysis assumes a continuation of the

practices, plan designs and delivery mechanisms that have led to the current situation. Thus the baseline analysis fundamentally assumes continuation of private health insurance and no immediate success in reducing inflationary trends that drive cost increases.

Costs

Claims data compiled from a representative selection of private sector plans was used to generate per capita claims that varied by age and sex. The resulting claims rates were tested against Alberta's population and adjusted so that they produced total costs that were consistent with the 2004 forecast referred to above.

Claim Projection Factors

Claim projection factors were developed for each age-sex cell by analyzing utilization and inflation patterns within the same representative selection of private sector plans and ensuring that the aggregate impact was consistent with increases typically required by private insurers at renewal. This process led to inflation factors that vary by age, sex and benefit sub-group as listed in the following table. It is not reasonable to assume that such high increases will continue indefinitely. As a result, for the five years following the year 2010, the initial projection factors were graded down into factors that were identical to those utilized in the non-emergency health model. Even with this moderating assumption, compounding leads to significant increases over time.

Claim Projection Factors

Total

The final adjusted per capita claims rates and inflation factors produced annual costs that increased from just over \$2 billion in 2006 to \$115 billion in 2050. As a per cent of taxable income, claims increased from 2.2% in 2006 to 17.25% in 2050. The equivalent level funding per cent was 7.76%. Note, however, that in a private insurance model, pre-funding has little applicability, because private insurers are unlikely to accept the attendant risks.

If not controlled, inflation threatens the affordability of health insurance in future.

Supplemental Health – Baseline Scenario

By Age

Costs per capita displayed a fairly consistent pattern. While costs for the age category zero-to-four were quite high, they declined for the next two or three age categories and began to rise thereafter, peaking at ages 90 and above.

Although per capita costs rose steeply by age, the distribution of covered population by age is such that older ages do not represent the bulk of the claims. Nevertheless, aging of the population is an additional cost driver, as more of the population lives longer.

Per capita cost rises very steeply with age. Nearly one-third of 2006 costs arise from those age 65 or more. This is projected to increase – the aging population has important implications for the cost of health care.

By Gender

Outside of the child-bearing years, per capita costs for females tended to be lower than for males. This pattern is consistent with other studies and was therefore not unexpected.

Supplemental Health – 2006 Per Capita Costs by Age and Gender

Total Cost by Age and Gender – 2006

Benefit	Age band	Male	Female	Total
ALL	0 - 4	24,723,886	19,498,443	44,222,328
ALL	5 - 9	30,498,265	25,413,583	55,911,848

		909,386,157	1,022,737,415	1,932,123,572

Despite generally higher male per capita claim rates, female utilization during the child-bearing years is such that in total females cost more in health care than males.

Mandatory Public Health Insurance

Key Cost Drivers

The following factors drive cost:

- Population growth;
- Aging population;
- New technology;
- Rising demand; and
- Provider expectations.

From page 2-12

The following graph displays the key sources of growth both through the year 2040 and over the entire projection period.

Supplemental Health – Sources of Growth

For supplemental health, claims inflation is the principal cost driver.

Sustainability

The current growth rate of costs under private insurance is not sustainable. Public insurance does not appear to offer greater scope for demand constraint than the current private model.

Opportunity for Choice

A public system would eliminate the opportunity for choice.

Opportunity to Link Behaviour

The mandatory public health insurance scenario offers little opportunity to link available health care to behaviour, unless the government wishes to consider brand new policy initiatives such as varying the coverage available by health status, e.g., obesity or smoking status, or contemplating the use of cost sharing or other user fees in reimbursing certain types of services.

Sensitivity Testing

No sensitivity testing of this scenario was conducted.

Conclusions

- Currently, these benefits are almost entirely privately insured. Given the anticipated growth rate of all medical care expenses and government's wish to reduce its exposure to such increases, it was decided that there was little

sense in performing any additional analysis of publicly funded scenario for these benefits.

Mandatory Public Health Insurance with Private Supplemental Coverage

Key Cost Drivers

The following factors drive cost:

- Population growth;
- Aging population;
- New technology;
- Rising demand; and
- Provider expectations.

Sustainability

The current growth rate of costs is not sustainable.

Opportunity for Choice

A public system would eliminate the opportunity for choice.

Opportunity to Link Behaviour

As in the previous scenario, the mandatory public scenario offers little opportunity to link available health care to behaviour.

Sensitivity Testing

No sensitivity testing of this scenario was conducted.

Conclusions

- Currently, these benefits are almost entirely privately insured. Given the anticipated growth rate of all medical care expenses and government's wish to reduce its exposure to such increases, it was decided that there was little sense in performing any additional analysis of publicly funded scenario for these benefits.

Mandatory Private Health Insurance

Since these benefits are currently privately provided, the mandatory private model bears certain similarities to the current situation.

This insurance model is based on the premise that government would mandate minimum benefits that would be required coverage for all Albertans through private carriers. Not all Albertans would be able to afford private premiums, so the model envisages the need for premium subsidies on a household means-tested basis. Private carriers would be free to establish their own costs for the plans they provided. Policyholders and/or plan sponsors would be

allowed to negotiate coverage beyond the regulatory minimums.

This system would closely resemble the current system, with the chief differences being that minimum coverage would be mandated and all Albertans would need to be insured for at least the minimum coverage.

In this scenario, the expected future inflation was reduced compared to the baseline scenario. As with non-emergency health care, maintaining unreduced future inflation led to costs that were clearly unrealistic and unsustainable. Therefore, revised inflation factors were developed for each age-sex cell and for each benefit grouping as follows:

- Initial inflation factors were unchanged for five years; and
- Beginning in 2011, annual reductions were assumed so that by the year 2015 the inflation assumption was identical to that assumed to apply to non-emergency health care under the mandatory public health insurance scenario.

Annual costs rise from \$2.1 billion in 2006 to \$63 billion in 2050. Expressed as a per cent of taxable income, the increase is still considerable – rising from 2.2% in 2006 to 8.8% in 2050. The equivalent level funding per cent is 5.6% of taxable income.

Success in limiting claims growth significantly increases affordability.

Supplemental Health – Comparison of Baseline and Mandatory Private Health Insurance

Private Scenario Cost Comparison

The projections above include the impact of co-payments, estimated to represent 10% of privately insured costs, in the overall costs. The following graph displays the annual costs and level costs which would fall to private insurers under this scenario, that is, they exclude co-payments. Note that co-payments reduce current costs by making patients share in their cost of treatment. However, they may also drive people to avoid needed care and thereby lead to much greater costs in future.

Key Cost Drivers

The following factors drive cost:

- Population growth; • New technology; • Provider expectations.
- Aging population; • Rising demand; and

Co-payments reduce the price of health insurance plans, but their long-term impact on cost is unknown.

Private carriers include a profit margin in their pricing, which is a factor that has no counterpart in public financing models. In addition, it may well be that moving from a single, centrally administered plan to one with decentralized administration offered by multiple sources will tend to drive administrative costs up. There is potential to offset this if private carriers succeed in negotiating provider arrangements that offer permanent, compounding savings compared to other models. In summary, this model appears to offer the likelihood of higher initial costs with possible future savings.

Sustainability

This model is as sustainable as the current optional private system of offering supplemental health insurance.

Opportunity for Choice

Consumers who purchase individual coverage would have freedom to choose the plan and the insurer that they wished, so this model offers maximum scope for individual choice. People who have insurance provided through a group insurance contract would be bound by the choice made by their employer, but the employer could choose from all carriers in the market.

Opportunity to Link Behaviour

The opportunity to link to behaviour in this scenario is a function of the plan design(s) mandated by the government.

Sensitivity Testing

The following additional scenarios have been tested:

- Ultimate inflation rate 1% higher, at 7%;
- Ultimate inflation rate 1% lower, at 5%;
- High population scenario;
- Low population scenario; and
- Salary indexation of 1% less for under age 65 and 0.5% less for age 65 or more.

The general conclusions are similar to those reached under the non-emergency health models. Low economic growth imposes the greatest burden on the population, with costs projected to exceed 14% of taxable income by the year 2050, followed by high inflation, under which costs approach 13% of taxable income by the year 2050. The other scenarios are relatively benign in their impact on the province's ability to absorb the projected increases.

Supplemental Health – Sensitivity Comparison

Conclusions

- This approach to providing supplemental health care coverage to the population enables all individuals to benefit from a floor of coverage.
- Recognizing that private insurers would consider some individuals to be uninsurable it would be prudent to hold advance discussions with representatives of the private industry to determine how best to ensure coverage for all and appropriate catastrophic coverage.
- The government would need to become involved in oversight to a greater degree than is currently the case.
- The modelling assumption of reduced future inflation has not been validated in practice.

Low economic growth and high claims inflation are major risks, but under this scenario they are borne by private industry.

Economic Analysis

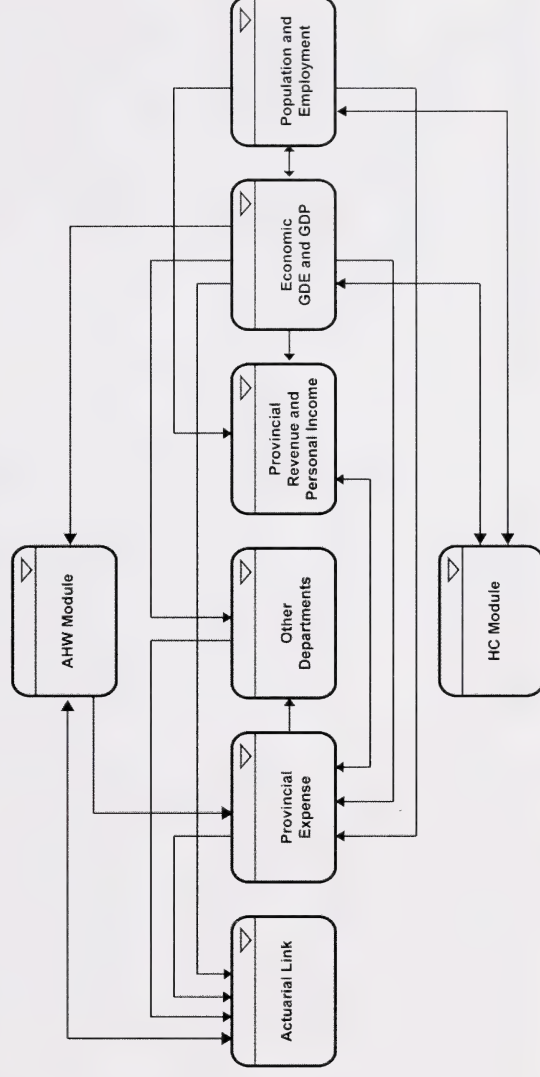

This document contains advice, proposals, recommendations, analyses or policy options developed for the Minister of Alberta Health and Wellness, and/or department of Alberta Health and Wellness.

Model Overview

The economic model uses a systems dynamic approach to simulate the economic effects associated with the baseline health care system and conceptual insurance models that have been actuarially modelled. This approach was adopted mainly to respond to the large number of causal factors that could be introduced with a large-scale change to the health care system. It also takes into account the high probability that this would degrade the reliability of analysis based on multivariate regression techniques.

*Chart 1. System Dynamic
Model Structure*

The economic model includes following primary modules:

- Population and Employment;
- Provincial Economy (GDE and GDP);
- Provincial Revenue and Expenses (Public Finance);
- Alberta Health and Wellness revenue and expenses;
- Contributions by Other Government Departments to Health Care;
- Economics of Health Care; and
- Actuarial Model Link.

The model includes approximately 400 variables. Of these, approximately 70 have manageable inputs for testing sensitivity, the impact of different assumptions and policy changes.

As a simulation, the model creates a number of dynamic loops that permit simulation of feedback relationships. The most significant of these are:

- Employment/unemployment and GDP; and
- Health care employment, productivity, health care GDP and provincial GDP.

Primary Data Sources

Data sources used in this model include:

- Alberta Finance's projected population model (three scenarios – high, medium and low);
- Alberta Finance's *Economic Model Projection 2002-2009* (specifically the key indicators were used to ensure that the key economic factors were aligned with current government projections);
- Provincial Expense based on *Historical Fiscal Summary of 2005-08 Fiscal Plan of the Budget 2005*;
- Alberta Health and Wellness Revenue and Expenses based on *Ministry Statement of Operations of the Business Plan 2005-08*;
- Other department contributions based on list of programs in Government of Alberta Ministries, not

including Alberta Health and Wellness that provide health funding.

- Historical data for the province found in *Health Care and Social Assistance GDP Statistics Canada data at Basic Price 1984-04 and Labor Force Survey 1976 -2005*.²⁷

The following section reviews the impact that key variables in the economic model have on the outputs. Note that in building on the current Alberta Finance Economic Projections and Demographic data, there are a number of implicit assumptions in the model that cannot be varied. These are noted below where appropriate.

Baseline Analysis

The baseline economic projection incorporates the baseline assumptions of the actuarial models. Furthermore, current taxation and other spending policies are deemed to be constant.

Provincial Finances

For the baseline projection, the key financial impact points for the province of Alberta are as follows:

- In 2016 provincial health care expenses could exceed 50% of the total provincial spending;
- Total provincial expenses may exceed revenue in

2017, putting the province in a deficit position; and

- Consistent deficit spending would eliminate accumulated net financial assets in 2025.

It is important to note that even with Alberta's projected revenue from natural resources, the projected increase in health care costs will still put the province in a deficit position within the projection period.

Health Care

Projected Fiscal Summary 2005 to 2025
Provincial Income Statement
(Millions of Dollars)

	Current Situation			
	2005	2010	2015	2020
Revenue				
Personal provincial tax	\$5,062	\$7,162	\$10,737	\$15,893
Business provincial tax	\$2,372	\$2,633	\$3,829	\$5,537
School property tax	\$1,268	\$1,417	\$1,643	\$1,905
Other tax revenue	\$1,920	\$2,444	\$3,347	\$4,557
Resource revenue	\$12,307	\$10,568	\$9,075	\$7,793
Investment income provincial revenue	\$1,404	\$2,674	\$3,068	\$2,610
Other own source revenue	\$4,114	\$5,238	\$7,171	\$9,762
Federal government transfers	\$3,413	\$4,409	\$5,900	\$7,895
Provincial Revenue	\$31,859	\$36,547	\$44,772	\$55,952
Expense				
AHW Expense	\$8,879	\$13,733	\$20,260	\$29,489
Health (other programs)	\$771	\$1,139	\$1,750	\$2,880
<i>Total Provincial health care funding</i>	<i>\$9,650</i>	<i>\$14,872</i>	<i>\$22,009</i>	<i>\$32,369</i>
Education	\$6,482	\$7,922	\$9,711	\$11,828
Social services	\$2,530	\$3,140	\$3,848	\$4,687
Other expense	\$6,298	\$7,139	\$8,751	\$10,659
Debt servicing cost	\$317	\$251	\$251	\$251
Total Provincial Expense	\$25,277	\$33,323	\$44,570	\$59,794
Assets				
Net Financial Assets beginning of year	\$16,580	\$39,056	\$46,947	\$37,770
Capital Assets beginning of year	\$10,640	\$12,850	\$15,224	\$17,976
Net Assets Beginning of year	\$27,220	\$51,907	\$62,171	\$55,746

With current trends, the province will shift to a deficit position in 2016/17 due to rising health care costs.

Canada Health Act Related Funding

Projected Fiscal Summary 2005 to 2025

Health Care Funding

(Millions of Dollars)

Funding	Current Situation			
	2005	2010	2015	2020
Public				
Alberta Health and Wellness	\$8,879	\$13,733	\$20,260	\$29,489
Other departments	\$771	\$1,139	\$1,750	\$2,880
Total Health Care Public Funding	\$9,650	\$14,872	\$22,009	\$32,369
Private				
Insurer funding	\$1,984	\$4,077	\$7,021	\$10,591
Out-of-pocket	\$1,192	\$2,277	\$3,690	\$5,462
Total Health Care Private Funding	\$3,176	\$6,354	\$10,711	\$16,053
Total Health Care Cost	\$12,827	\$21,226	\$32,721	\$48,422
Use of Funds				
Prescription drugs cost	\$2,735	\$5,698	\$9,316	\$13,697
Continuing care cost	\$1,263	\$1,749	\$2,269	\$3,196
Non-emergency cost	\$4,714	\$7,378	\$11,454	\$17,793
Supplementary health cost	\$1,830	\$3,621	\$6,221	\$9,402
Other health care	\$1,900	\$2,317	\$2,929	\$3,710
Total Health Care Cost	\$12,827	\$21,226	\$32,721	\$48,422
				\$72,105

For the baseline projection, the most significant trend is private health spending as a portion of total spending due to above average utilization and inflation for supplemental health and prescription drugs.

GDP Impact on Sustainability

Federal government funding for health care is a significant component of the province's funding. Using the baseline scenario, the total loss of such funding, no matter how unlikely, would shift the deficit break-even point from 2017 to 2010/11 (assuming there are no other changes to revenue).

Apart from controlling cost, the growth of the provincial economy is the most significant factor in ensuring sustainable health care. An average real GDP growth rate of 3.5% (until 2025) would be required to prevent a deficit position.

Other Program Cost Impact on Sustainability

The baseline projection largely assumes that non-health costs for the Government of Alberta will increase proportionately to increases in the CPI and population growth. Testing with a non-health care cost growth of the CPI only, implying a reduction in other services, delayed the shift to a net deficit until 2023/24, but did not change the overall trend towards a non-sustainable position.

Similarly, with the higher GDP growth rate and avoidance of a deficit position, the province's net financial assets are maintained and can continue to contribute to revenue through investment income.

The baseline projection largely assumes that non-health costs for the Government of Alberta will increase proportionately to increases in the CPI and population growth.

Selected Insurance Plan Impacts

Projections associated with different insurance plans have material impact on sustainability. The specific nature of this effect is largely related to any tax policy changes that would offset a portion of the additional revenue or reduced costs linked to specific insurance models.

Prescription Drugs

The following table summarizes the potential economic impact of the public mandatory insurance with private replacement conceptual model where applied to prescription drugs.

If premiums collected are in addition to current revenue, there is a significant effect as the growth in costs associated with prescription drugs is completely offset with new revenue. As this would have the effect of a large increase in personal taxes, other policy changes would be necessary.

Giving premiums a tax-deductible status has a minor impact on the total surplus as personal income tax rates are relatively low.

Fully offsetting new premiums with a tax reduction would slightly worsen public finances as this is done in conjunction with increased prescription drug costs for the province (slightly increased use for those currently uninsured or under-insured). Any offsetting taxes would

need to carefully balance the impact on individuals receiving insurance through their employer and those who would be obtaining insurance through a public provider.

Prescription Drugs			
Scenario	Health Care/Provincial Revenue		Net Revenue (millions)
	2005	2025	2025
Baseline	30%	68%	(\$10,432)
Public with Private Replacement	29%	53%	\$11,976
Public with Private Replacement (with premiums considered tax-deductible)	29%	54%	\$9,704
Public with Private Replacement (taxes reduced to account for increased premiums)	30%	72%	(\$13,112)

Continuing Care

The following table summarizes the potential economic impact of the public mandatory conceptual model as applied to continuing care.

If premiums collected are in addition to current revenue, there is a material effect on net revenue that greatly delays the deficit breakeven point. Note, however, that this is essentially analogous to an increase in personal taxes.

- As this is a mandatory public plan, there is no material impact on costs if the insurance premiums are offset with tax reductions.
- Prior to 2025, pre-funding has no material improvement over the basic mandatory public insurance model. However, as the impact of population aging largely takes place in the 2020 – 2040 period, the longer-term sustainability would be enhanced.

Continuing Care

Scenario	Health Care/Provincial Revenue		Net Revenue (millions)	
	2005	2025	2005	2025
Baseline	30%	68%		(\$10,432)
Mandatory Public (no pre-funding)	30%	61%		(\$2,101)
Mandatory Public (no pre-funding and taxes reduced to account for increased premiums)	30%	68%		(\$10,432)
Mandatory Public (with pre-funding)	30%	61%		(\$1,948)

Non-Emergency Health

The following table summarizes the potential economic impact on non-emergency health of a private mandatory insurance with public premium pooling model.

Where productivity gains enabled by the competition encouraged by private insurers meet the actuarial projections, there is a substantial improvement in the province's net revenue position.

The portion of health care within the public sector dramatically decreases (relative to the baseline projection for 2025) as a large portion of health care costs are not paid from the general revenue fund in this scenario. These costs still exist but there is no additional private sector burden, only the funding mechanism changes. Should all federal transfers be eliminated with this model, there would be an anticipated worsening of public finances, as productivity gains would not offset the lost funding.

Non-Emergency Health

Scenario	Health Care/Provincial Revenue		Net Revenue (millions)	
	2005	2025	2005	2025
Baseline	30%	68%		(\$10,432)
Private with Public Pooling (taxes reduced to account for increased premiums)	30%	28%		(\$3,691)
Private with Public Pooling (taxes reduced to account for increased premiums and elimination of federal transfers)	30%	32%		(\$11,204)

Other Comments

Based on current projections, rising health care costs would create a deficit for the Government of Alberta by 2017. The primary factors for improving this are:

- Economic growth above baseline projections, increasing provincial revenue sufficiently to offset the increase in costs. Sensitivity testing indicates

- that a long-term rate of 3.5% real growth is required.
- Reducing health care costs beyond those estimated in the base actuarial projections. Ideally this will be done by increasing productivity through operational improvements or additional capital investment, limiting growth in health care labour requirements and subsequent wage inflation pressures.
 - Offsetting increases in health care costs with a net increase in revenue to the health care sector, either through increased taxes or new health insurance premiums (that are not fully offset by tax reductions). This may impact Alberta's relative tax level, requiring careful balancing of any increase in costs with the relative taxes and premiums levied in other jurisdictions.

Methodology Overview

Unemployment – GDP Relationship

The summary table includes results of regression analysis of relationships between unemployment and GDP growth based on historical annual data of Statistics Canada (*Labor Force Survey 1981-2004 and GDP 1981-2004*).

Summary Table

Variable	Coeff.	Std.Err.	t Stat.	P-value	Lower 95%	Upper 95%
Intercept	0.026	0.009	2.786	0.014	0.006	0.046
GDP growth	-0.159	0.032	-4.974	0.000	-0.227	-0.091
unempl_1st	1.526	0.153	9.952	0.000	1.199	1.853
unempl_2nd	-0.781	0.169	-4.632	0.000	-1.141	-0.422
unempl_4th	0.102	0.061	1.673	0.115	-0.028	0.232

Regression Statistics

Multiple R	R Square	Adj. R Squ	Std. Err.	# Cases	# Missing	Deg. Free	t(2.5%, 15)
0.979	0.957	0.946	0.009	20	4	15	2.131

Based on the regression there is a clear loop between unemployment and GDP, and these results were used to absorb the component of unemployment related to GDP growth. Furthermore, unemployment was defined as a function of the sum of the historically performed part of unemployment and a component related to GDP growth (with negative coefficient 0.159).

Health Care Module Sensitivity Testing

To analyze accumulated impact for the 2006-2025 time period, sensitivity analysis was conducted for the *Sum of Real Health Care GDP* (in Constant 1997 Dollars). The critical factors for Health Care GDP are productivity and employment in health care (assuming level unemployment rates). In both cases a 1% increase contributes to 12% growth in the Sum of Real Health Care GDP.

Note that productivity, which is defined as a function of GDP divided by working hours, and employment contributions to GDP have a proxy effect on the used capital stock influence. Essentially, one expects the 2006-2025 Sum of Real Health Care GDP to increase by 12% in response to a 1% increase in employment. This is due to the assumption that there is sufficient capital stock to ensure the larger labour force's productivity rate is unchanged. Even with the proxy effect, productivity growth is found to be a major factor in increasing Health Care GDP.

Insofar as there is a significant difference in productivity, and that health care workers are highly educated (minimizing an education effect), the productivity gap is largely defined by:

- Lack of available or used tools to work more productively; and/or
- Sub-optimal operational efficiency level.

Productivity growth is a key factor for cost effective increases to Health Sector GDP.

Input Variable	Input Values			Output Values (Sum of Real GDP \$97M 2005-2025)					Per Cent Variance
	Low	Base	High	Low	Base	High	Change	Swing	
Productivity growth after 2009	0.53%	1.48%	2.66%	161,190	172,899	189,054	9.3%	27,864	37.0%
Population projections (1-low, 2-medium, 3-high)	1	2	3	165,081	172,899	186,430	7.8%	21,350	21.7%
Additional growth of health care employment	0.00%	0.00%	1.00%	172,899	172,899	193,585	12.0%	20,686	20.4%
Additional growth of health care productivity	0.00%	0.00%	1.00%	172,899	172,899	193,523	11.9%	20,624	20.3%
Unemployment rate	3.90%	3.90%	5.30%	172,899	172,899	170,785	-1.2%	2,114	0.2%
Additional net in-migration/population	0%	0%	1.04%	172,899	172,899	174,697	1.0%	1,798	0.2%
Participation rate	72.84%	73.21%	73.56%	172,157	172,899	173,584	0.4%	1,427	0.1%
Hours per year	1804.58	1820	1820	171,670	172,899	172,899	0.0%	1,229	0.1%

Sensitivity Analysis

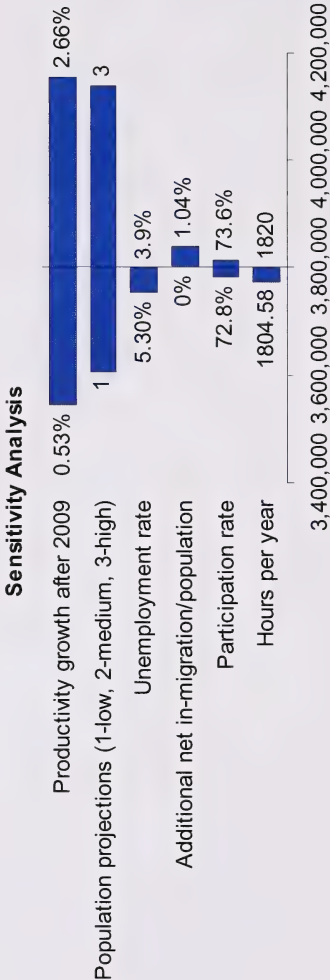

Sum of real HC GDP \$97M 2006-2025

Provincial Economy Sensitivity Testing

The sensitivity chart above provide analysis of 2006-2025 Sum of Real Alberta GDP (in Constant 1997 Dollars). As is the case with Sum of Real Health Care GDP, productivity and employment growth are highly correlated with the GDP projections. Thus, an increase in productivity after 2009 by 1.18% increases the Sum of Real Alberta GDP by 9.34%. Switching to the high projection of population increases Sum of Real Alberta GDP by 8.94%.

Input Variable	Input Values				Output Values (Sum of Real GDP \$97M 2005-2025)			
	Change	Low	Base	High	Change	Low	Base	High
Productivity growth after 2009	-0.95%	0.53%	1.48%	2.66%	1.18%	3,543,007	3,800,125	4,154,881
Population projections (1-low, 2-medium, 3-high)								
Unemployment rate	0.00%	3.90%	2	3	1.40%	3,605,352	3,800,125	4,139,735
Additional net in-migration/population	0.00%	0%	0%	1.04%	1.04%	3,800,125	3,800,125	3,839,647
Participation rate	-0.37%	72.8%	73.2%	73.6%	0.35%	3,783,838	3,800,125	3,815,170
Hours per year	-0.85%	1804.58	1820	1820	0.00%	3,773,131	3,800,125	3,800,125

Productivity and population growth dominate GDP projections where full employment is assumed.

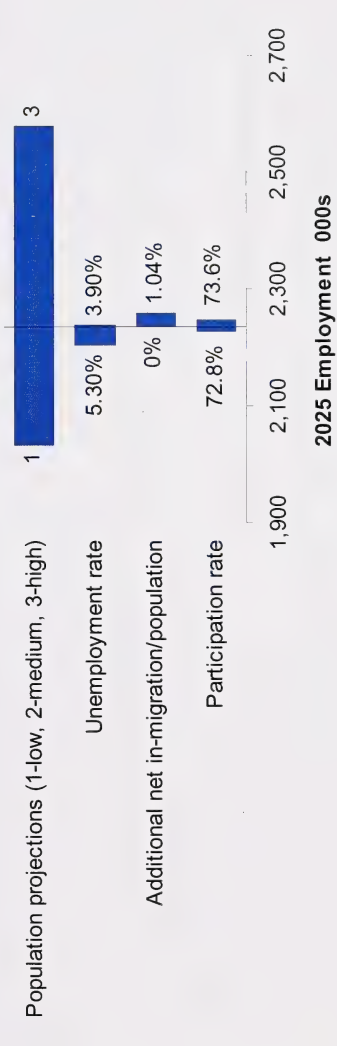

Employment Sensitivity Testing

Full employment is a major source of high GDP growth, assuming that the capital stock is sufficient to utilize a growing labour force without decreasing current productivity levels. As indicated in the following chart, variations in the population projections provided by Alberta Finance are the primary determinants of this module's variability. If the assumptions underlying this demographic projection are realized, the increased population growth could create a 15.27% increase in employment growth by 2025. Given the assumptions of the population projection, it is not surprising that the changes to the unemployment rate are relatively linear (i.e., an increase of 1.4% in unemployment creates a reduction in total employment of 1.46% by 2025).

Input Variable	Input Values			Output Values (Sum of Real GDP \$97M 2005-2025)		
	Change	Low	Base	High	Change	Low
Population projections (1-low, 2-medium, 3-high)		1	2	3		
Unemployment rate	0.00%	3.90%	3.90%	5.30%	1.40%	2,032
Additional net in-migration/population	0.00%	0%	0%	1.04%	1.04%	2,237
Participation rate	-0.37%	72.8%	73.2%	73.6%	0.35%	2,225
						2,237
						2,260
						2,247
						15.27%
						-1.46%
						1.04%
						0.47%

Sensitivity Analysis

The model's employment data is heavily influenced by the assumptions in Alberta Alberta Finance's population projections.

Provincial Government Revenue

The model does not reflect the impact of changes to the implicit tax rate on productivity and economic growth.

Should a relationship between the implicit tax rate and productivity be identified, the model can be subsequently extended to accommodate this.

Health Outputs

There are suggestions that improvements in population health positively impact productivity and employment participation rate, leading to GDP growth. With the data available to this study, no strong relationship function could be identified between health outputs and productivity or GDP. Such analysis could be improved by additional data on capital stocks and other parameters impacting productivity. Furthermore, the time frame of the data could be extended (data permitting) to account for the considerable lag between improvement in health outcomes and economic impact.

General Comments on Multiplier

A reliable regression could not be found where the multiplier could be more than one within the scope of the analysis.

Vignettes

This document contains advice, proposals, recommendations, analyses or policy options developed for the Minister of Alberta Health and Wellness, and/or department of Alberta Health and Wellness.

Overview

The purpose of these illustrations is to demonstrate the expected pattern of funding contributions, available income and projected costs for a selection of representative households at different points in time. In each case, the costs and expected claims are carried forward to capture the anticipated results associated with the household, as the individuals in it age.

Five households, designed to capture a range of differently situated individuals or families were modelled:

- Lance Lake, single male, aged 22
- Joseph and Mary Allison, aged 32, two children, boy aged seven and girl aged two
- Daniel and Celeste Denison, aged 42, with three children, boy aged 17, girl aged 12 and boy aged seven
- Arthur and Jenn King, aged 52, no children
- Jessica Langley, pensioner, aged 72

In each scenario, an appropriate average income was assumed for the individual or household.

The analysis compares expected average costs to the health care system, financing contributions and net income at different future points in time. It captures changing relationships among these three items as circumstances change in normal age-related patterns.

The points in time selected for comparison were 2006, 2020 and 2040.

The modelling includes prescription drugs, continuing care and non-emergency health. Supplemental health was not included in the model as it is already provided privately.

Vignette 1

Lance Lake is a 22-year old single male in 2006. Over time, his projected funding contributions, costs and net income are as follows:

	2006		2020		2040	
Funding contribution	\$3,042	25%	\$21,471	29%	\$54,027	29%
Health service costs	\$953	8%	\$3,835	5%	\$31,927	17%
Net income	\$12,100	100%	\$75,000	100%	\$189,000	100%

By 2040, Lance has reached age 56, but he has yet to cost the system more than he has contributed to it. This illustrates the generational transfer of costs that results from implementing level funding for all. Lance's funding contribution is greater than the amount needed to pay for his own costs, because he also needs to pay for the increased utilization on the part of those currently older than he is.

Vignette 2

Joseph and Mary Allison are a young couple, both aged 32 in 2006, with two children, a son aged seven and a daughter aged two. Over time, their projected funding contributions, costs and net income are as follows:

	2006		2020		2040	
Funding contribution	\$14,757	26%	\$42,423	35%	\$28,546	28%
Health service costs	\$5,800	10%	\$18,226	15%	\$90,387	89%
Net income	\$57,600	100%	\$122,000	100%	\$102,000	100%

By 2040, at age 66, Joseph and Mary will have begun to cost the system more than they contributed to it. The crossover point occurs, roughly, at age 60. Note that since costs are projected to grow more rapidly than income, the gap between the two is expected to grow over time.

Vignette 3

Daniel and Celeste Denison are a middle-aged couple, both aged 42 in 2006, with three children, a son aged 17, a daughter aged 12 and a second son aged seven. Over time, their projected funding contributions, costs and net income are as follows:

	2006		2020		2040	
Funding contribution	\$19,308	30%	\$37,917	31%	\$27,329	28%
Health service costs	\$5,978	9%	\$19,456	16%	\$165,651	167%
Net income	\$65,000	100%	123,000	100%	\$99,000	100%

Vignette 4

Arthur and Jenn King are an older couple, both aged 52 in 2006. Their children are adults, who no longer live with their parents. Over time, their projected funding contributions, costs and net income are as follows:

	2006		2020		2040	
Funding contribution	\$11,017	28%	\$9,305	26%	\$13,427	26%
Health service costs	\$5,309	13%	\$27,306	76%	\$214,065	412%
Net income	\$40,000	100%	\$36,000	100%	\$52,000	100%

Shortly after 2006, Arthur and Jenn's received health services exceed their contribution. This amount becomes extremely large over time. In essence, they benefit from the excess contributions paid by younger individuals like Lance Lake.

Vignette 5

Jessica Langley is a single pensioner, aged 72 in 2006. Over time, her projected funding contributions, costs and net income are as follows:

	2006		2020		2040	
Funding contribution	\$4,799	25%	\$6,196	26%	N/A	N/A
Health service costs	\$6,872	36%	\$37,955	158%	N/A	N/A
Net income	\$19,000	100%	\$24,000	100%	N/A	N/A

Throughout the projection period, Jessica is expected to cost the system more than she contributes.

Vignettes – Summary Observations

The five vignettes illustrate several characteristics of level percentage financing costs:

- The fact that no previous pre-funding has been conducted means that the vast majority of the current population will not fund their own costs over their remaining lifetime. Consequently, the funding rate for younger individuals is higher than it would be if they only needed to fund their own lifetime costs.
- The required funding contributions are significant. Taken as a whole, they divert very large amounts of money within the economy from consumption into forced savings.

Additional Analyses

Overview

In recognition of the fact that Alberta expects to produce budget surpluses for the next several years, the impact on pre-funding was modelled, should some of the available surplus be committed towards reducing the cost of pre-funding. Various possibilities were considered; the following were adopted:

- Single amounts available in 2006:
 - \$1 billion for each benefit grouping
 - \$2 billion for each benefit grouping
 - \$5 billion for each benefit grouping
 - \$10 billion for each benefit grouping
- Recurring amounts (for five years):
 - \$1 billion for each grouping
 - \$2 billion for each grouping
 - \$5 billion for each grouping

Note that for these purposes, supplemental health was not included in the model as it is already provided privately.

In addition to the above, the decision was made to test the impact of a government endowment of required funding contributions. The available endowment was assumed to be either \$5 billion or \$10 billion in total. In each case it was assumed to be applicable for either five or 10 years.

The above scenarios tested the impact of different levels of government support for the overall funding system. In addition to this testing, given the potentially negative impact of the pre-funding charge needed to provide for all costs incurred to 2050, alternative approaches to pre-funding were modelled:

- Pre-fund only the first 10 or 20 years of projected costs.
- Determine the “step-up” level per cent necessary to pre-fund costs over consecutive 10-year periods. This approach tested the possibility that the economy might be better able to tolerate gradual increases in the funding rate, rather than the abrupt increase needed to pre-fund through to 2050.
- Test the impact of a three-year deferral of pre-funding.
- Test the cost impact to the province of possible endowments for the insurance models.

Scenarios

1. Differing levels of government financing support for the population as a whole

The results of the different types and amounts of government support are summarized in the following table:

	Prescription Drugs	Continuing Care	Non- Emergency	Total Endowment
Mandatory Public – No Support	7.98%	2.39%	12.16%	N/A
One-Time \$1B	7.95%	2.36%	12.13%	\$3B
One-Time \$2B	7.93%	2.34%	12.11%	\$6B
One-Time \$5B	7.85%	2.26%	12.03%	\$15B
One-Time \$10B	7.72%	2.13%	11.90%	\$30B
Recurring \$1B	7.86%	2.27%	12.04%	\$15B
Recurring \$2B	7.75%	2.16%	11.93%	\$30B
Recurring \$5B	7.40%	1.81%	11.58%	\$75B
\$5B Endowment – 5 years	6.89%	1.30%	11.10%	\$15B
\$5B Endowment – 10 years	7.44%	1.85%	11.63%	\$15B
\$10B Endowment – 5 years	5.81%	0.22%	10.04%	\$30B
\$10B Endowment – 10 years	6.90%	1.31%	11.11%	\$30B

Note – After either five or 10 years in the last four scenarios above, the funding percentage reverts to the full contribution required for the benefit group.

The projected costs grow so rapidly that it is very difficult for the government to materially reduce them without advance commitments of very large amounts of money. The last four scenarios above display the impact of different levels of government endowment of the total funding costs on the population. This may not be the most useful way to illustrate these results. Consider the following graph:

The graph above shows that projected temporary endowments can have a noticeable impact on the costs to the population over either the first five years or the first 10 years. Even with these endowments, the costs required to pre-fund to 2050 are significant – they would not be easily carried by the population.

2. Differing approaches to pre-funding

- Defer for three years:

	No Deferral	Three-Year Deferral
Prescription Drugs	7.98%	8.89%
Continuing Care	2.39%	2.49%
Non-Emergency Health	12.16%	13.23%

If Alberta is interested in implementing pre-funding, this must be done quickly. The price of delay will be significant.

- Shorten the pre-funding period:

	To 2050	10 years	20 years
Prescription Drugs	7.98%	3.85%	4.84%
Continuing Care	2.39%	1.53%	1.64%
Non-Emergency Health	12.16%	6.55%	7.79%

Shortening the pre-funding period appears to offer mixed prospects. The projected costs for continuing care look quite manageable. However, continuing care is the least expensive of the benefit groups. Results for prescription drugs and non-emergency health are not economically viable.

- “Step-up” level per cent funding:

	To 2015	To 2025	To 2035	To 2045	To 2050
Prescription Drugs	3.85%	5.84%	8.15%	11.52%	15.07%
Continuing Care	1.53%	1.75%	2.64%	3.35%	3.37%
Non-Emergency Health	6.55%	9.02%	12.65%	17.32%	20.97%

Unless a means can be discovered to reduce growth in costs, “step-up” pre-funding does not appear to have enough impact to significantly reduce the burden on the population. In addition, the adoption of such a system requires the implementation of future increases, which would need to be justified to and accepted by the population.

3. Permanent Population Subsidies

Should Alberta choose to adopt any form of premium payment as the basis for providing for the costs of public health care, those without the financial means to pay for their own insurance would require financial support. The specific system adopted is a decision to be taken by the Alberta government and must necessarily reflect a mix of policy, social and financial considerations. For example, any system that is based on excluding the first \$X of income for the entire population for funding purposes is liable to exclude an amount of income so large, that the resulting contributions would be completely unsupportable. A system was tested in which:

- Those with less than \$10,000 in taxable income are fully subsidized;
- Those with \$10,000 or more of taxable income but less than \$20,000 are partly subsidized; and
- Those with \$20,000 or more of taxable income are not subsidized at all.

In this system, the cost of subsidies was limited to 2.2% of total costs.

The following tables show the impact of subsidies on level funding requirements.

Funding Comparison for 2006

Benefit Grouping	Level Funding Per Cent	Level Funding with Subsidies	Impact of Subsidies
Prescription Drugs	7.98%	8.16%	0.18%
Continuing Care	2.39%	2.44%	0.05%
Non-Emergency Health	12.16%	12.43%	0.27%

Annual Cost Comparison (\$'000,000's)

	Year							
	2006	2007	2008	2009	2010	2015	2020	2025
Prescription Drugs								
Level funding without subsidies	7,431	7,852	8,312	8,769	9,245	11,859	14,970	18,613
Subsidy required	167	177	187	197	208	267	337	419
Continuing Care								
Level funding without subsidies	2,225	2,351	2,489	2,626	2,768	3,551	4,483	5,574
Subsidy required	50	53	56	59	62	80	101	125
Non-Emergency Health								
Level funding without subsidies	11,325	11,966	12,668	13,364	14,089	18,074	22,815	28,367
Subsidy required	255	269	285	301	317	407	513	638

Actuarial Methodology

This document contains advice, proposals, recommendations, analyses or policy options developed for the Minister of Alberta Health and Wellness, and/or department of Alberta Health and Wellness.

Population

The population of Alberta was projected until year 2050 for cost projections and financing purposes. These projections take into account mortality improvements as well as net emigration.

Projections were derived based on Alberta Finance's three projections: Low, Medium and High. (See Tables 1.1 to 1.3)

Note that Alberta Finance's projections give the number of persons per gender and five-year age-bands, from age-band 0-4 to age-band 95+, from the years 2003 to 2026. These projections do not include any mortality improvements.

Projection of Age-bands 0-4

From the Alberta Finance data, "0-4 age-band generating ratios" over five-year periods, were defined as the number of persons in age-band 0-4 in year $y+5$ divided by the number of women between the ages of 20 and 39 in years $y+1$ to $y+5$. The ratios derived for year $y+5 = 2026$ have been assumed to remain the same in following years. These ratios have been used to project the 0-4 age-bands until year 2081.

Projection of Age-bands 5-9 to 60-64

From the Alberta Finance data, "cohort replacement ratios" over five-year periods, were defined as the number of persons in age-band $(x+5)-(x+9)$ in year $y+5$ divided by the number of persons in age-band $(x)-(x+4)$ in

year y . This was done for $x=0$ to $x=55$ and for $y=2003$ to $y=2021$. These ratios take into account mortality without improvement and net emigration.

For the same cohorts, the cohort replacement ratios over five-year periods were taking into account mortality without improvement, and no migration. This has been done based on Alberta's mortality rates for years 1995-1997, published on Statistics Canada's website:

[http://www.statcan.ca/francais/freepub/84-537-](http://www.statcan.ca/francais/freepub/84-537-XIF/tables/txttables/altam_f.txt)

[XIF/tables/txttables/altam_f.txt](http://www.statcan.ca/francais/freepub/84-537-XIF/tables/txttables/altam_f.txt) and

[http://www.statcan.ca/francais/freepub/84-537-](http://www.statcan.ca/francais/freepub/84-537-XIF/tables/txttables/altaf_f.txt)

[XIF/tables/txttables/altaf_f.txt](http://www.statcan.ca/francais/freepub/84-537-XIF/tables/txttables/altaf_f.txt). (See Table 1.4)

Net emigration ratios were then derived. The net emigration ratios for year 2026 have been assumed to remain the same in following years.

Mortality improvement factors were used as defined in the Scale AA published in Transaction of Society of Actuaries 1995, Vol. 47. (See Table 1.5)

Finally, mortality improvement factors were combined with net emigration ratios to project the population until year 2081.

Projection of Age-bands 65-69 to 95+

From the Alberta Finance data, "cohort replacement ratios" over five-year periods, were defined as the number of persons in age-band $(x+5)-(x+9)$ in year $y+5$ divided by the number of persons in age-band $(x)-(x+4)$ in year y . This was done for $x=60$ to $x=90$ and for $y=2003$ to

y=2021. These ratios take into account mortality without improvement. No migration for ages over 65 was also assumed.

The ratios derived for year $y+5 = 2026$ have been assumed to remain the same in following years.

For years 2008 and onwards, mortality improvement factors were used as defined in the Scale AA published in Transaction of Society of Actuaries 1995, Vol. 47, in order to modify the ratios calculated above and to project the population until year 2050.

Final Results

Final values were rounded to the closest five units. (See Tables 1.6 to 1.8)

Income

Income for the entire population of Alberta was projected.

Income per Individual

Income per individual was projected based on data provided by Canada Revenue Agency (CRA) for the 2002 tax year on its website <http://www.cra-arc.gc.ca/agency/stats/gb02/pst/final/pdf/ab/table6-e.pdf>. (See Table 2.1) Based on the general population data, the number of individuals without any income was derived in each age-band.

According to the Government of Alberta projections, the population's total personal income is estimated to have increased by 25.2% from 2002 to 2006. In order to

replicate this increase, CRA's data to tax year 2006 was projected by using an increase rate of 4% per annum for the income of persons aged less than 65, and an increase rate of 2% per annum for the income of persons aged 65 and over. The distribution of income by age-band and income-band for year 2006 was then derived. (See Tables 2.2 and 2.3)

Income per Household

The income per household was projected based on data provided by Statistics Canada for the 2003 tax year for households with one and two adults separately. (See Table 2.4)

As was done for income per individual, Statistics Canada's data to tax year 2006 was projected by using an increase rate of 4% per annum for the income of persons aged less than 65, and an increase rate of 2% per annum for the income of persons aged 65 and over. The distribution of income by age-band and income-band for year 2006 was then derived. (See Tables 2.5 and 2.6)

Consistency

Consistency between projected income per individual and projected income per household was verified.

Projection to Future Years

It was assumed that the income of persons aged less than 65 will increase at a rate of 4% per annum, and that the income of persons aged 65 and over will increase at a rate of 2% per annum.

It was also assumed that the income of households where the older partner is aged less than 65 will increase at a rate of 4% per annum, and that the income of households where the older partner is aged 65 or more will increase at a rate of 2% per annum.

It was assumed that, within an age-band, the proportion of individuals or households in each income-band would remain the same as in year 2006 for the following years.

Commentaries on Income Increases

It was assumed that the income of active persons would increase at an annual rate equal to the general consumer price index (CPI) plus 1% to recognize productivity gains. Moreover, it was assumed that, after age 65, income would increase at a rate equal to half the increase rate used for active persons, in order to take account of the fact that some private pensions are not indexed or are partially indexed, and that some government program pensions are indexed at the CPI rate.

These assumptions are consistent with the fact that the average CPI was close to 3% in Alberta from 2002 to 2005. Furthermore, it was assumed that the CPI in Alberta would be equal to 3% in the future years.

Public/Private Differential

It can safely be stated that the substitution of private insurance for public is likely to alter the projected stream of costs. What is more difficult to predict is the total

impact of such a substitution. In summary, the following are principal considerations:

- Private insurance will include profit margins.
- Under private insurance there may be increased administration margins (first because a single-payer system is replaced by a multiple-payer system and second because private insurers will likely have sources of administrative costs that public insurers will not have e.g., enrolment and billings, actuarial valuation, underwriting and sales).
- Private insurers may have a greater incentive to manage claims costs than a public carrier would, which may mean that savings would emerge over time to offset at least some of the first two items in the example above.

It is believed that the savings outlined in the third bullet above will not arise in connection with prescription drug benefits. This is because drug costs are principally driven by pharmaceutical pricing practices rather than by items like productivity that are perhaps more amenable to insurer control or influence. Thus when moving from public to private, the expected impact is an initial increase with the possibility of future savings, if the private insurers are successful in limiting cost inflation in the future.

Prescription Drugs

Drug costs are made of the sum of the following groups:

- Prescribed drugs:

Alberta Health and Wellness sponsored drug plans, including Alberta Health and Wellness contracts with Alberta Blue Cross to offer three supplementary health plans for the following client groups:

Non-Group Coverage, available to all Albertans under the age of 65 years, and their dependants;

Coverage for Seniors, for all Albertans 65 years of age and older and their dependants, and for recipients of the Alberta Widows' Pension and their dependants; and

Palliative Care Drug Coverage, for people diagnosed as being palliative and receiving their treatments at home.

Other Alberta ministerial drug benefit programs:

Alberta Human Resources and Employment;

Alberta Children's Services and Alberta Seniors; and

Community Supports (AISH) clients.

Alberta government-sponsored drug programs:

The Alberta Blue Cross Non-Group Coverage (Group 1) offered by the Alberta Health Care Insurance Plan;

The Alberta Blue Cross Coverage for Seniors (Group 66) provided to all Alberta senior citizens and those on the Alberta Widows' Pension Plan (Group 66A);

The drug coverage provided to individuals approved by Alberta Health and Wellness for Palliative Care Drug Coverage (for these individuals the Palliative Care Drug Benefit Supplement must also be considered); or

The drug coverage provided to Alberta Human Resources and Employment,

Alberta Children's Services and Alberta Seniors and Community Supports (AISH)

clients (for these clients the Alberta Human Resources and Employment Drug Benefit Supplement must also be considered).

Indirect Government of Alberta drug spending:

Cancer drugs; and

Province Wide Services (HIV, transplant drugs).

- Non-prescribed drugs.

Incidence Rates

Incidence rates will vary differently from one therapeutic class to another. For each of the 10 therapeutic class groupings used (see Table 3.1 in Appendix), relative incidence rates were established in year 2020 and these rates were interpolated linearly between 2006 and 2020. (See Table 3.2 in Appendix). It was assumed that the 2020 rates will remain the same for the future years. Incidences rates were established per five-year age-band and per gender. Incidence rates were established at 100% from 2004 to 2006.

Costs for Year 2004

Since, as previously mentioned, incidence rates will vary differently from one therapeutic class to another, average drug costs were determined per person, for various therapeutic class groupings. In order to take account of expected variations in the Alberta population demography, average drug costs were established per five-year age-band and per gender.

Comprehensive data on claims submitted to Alberta Health and Wellness (AHW) programs for the 2004-2005 fiscal year were received from Alberta Health and Wellness. Based on Table 4.3 of AHW Alberta Health Care Insurance Plan Statistical Supplement 2003/2004, first the number of members in AWH programs in fiscal year 2004-2005, and then the average prescribed drug costs per age-band were projected. Since the AHW data provided eligible claim as well as paid claim information,

cost sharing between the government and the insureds were derived. (See Table 3.3)

Comprehensive data on claims submitted to income support programs for the 2004-2005 fiscal year were received from the Government of Alberta. Based on the number of members provided in the AHW presentation "Consolidation of Government of Alberta Drug Benefit Programs" dated November 1, 2005, the distribution of prescribed drug costs per age-band were derived. Since Government of Alberta's data provided eligible claim as well as paid claim information, the cost sharing between the government and the insureds were derived. (See Table 3.4)

Details on prescribed drugs paid under the special drug programs were not received, except for the total amount paid in the 2004-2005 fiscal year. It was assumed that the special drug programs prescribed drug costs would be proportional to the sum of prescribed drug costs paid under the AHW and the income support programs. This proportion has been established to be 57.5%.

Based on the table on page 94 in the Canadian Institute for Health Information (CIHI) document titled "Drug Expenditure in Canada 1985 to 2004", the total prescribed drug costs incurred by uninsured persons and persons under private insurance were derived.

According to the AHW presentation "Consolidation of Government of Alberta Drug Benefit Programs" dated November 1, 2005, 27% of Albertans do not have

supplemental coverage for community prescription drugs. The age and gender characteristics of these persons were determined based on Albertans that declared having no prescribed drug coverage in the Canadian Community Health Survey Cycle 2.1 (2003). It was assumed that, within each age-band and gender cell, these uninsured persons would use prescribed drugs at a rate close to the Alberta population average. (See Table 3.5)

The number of persons covered under private insurance was derived as the difference between the entire population of Alberta and the sum of the uninsured persons and the populations covered under AHW and income support programs. In addition, the prescribed drug costs incurred under private insurance were derived as the total prescribed drug expenditure projected by CIHI minus the prescribed drug costs incurred by the uninsured persons and the various government programs. In order to determine average costs per age-band, the statistical information of a representative selection of private sector data was used. (See Table 3.6)

Finally, non-prescribed drug projections were based on CIHI's projection for 2004. It was assumed that, within each age-band and gender cell, the non-prescribed drug cost would be proportionate to the cost of all prescribed drugs. (See Table 3.7)

Rates of Increase

Various sets of rates of increase were used:

- For prescribed drugs:

For the baseline projection, a flat inflation rate equal to CPI + 12% per annum was used to project drug costs assuming that the inflation rates observed in the last few years would remain the same in the future. This rate was combined with incidence rates and demographic variations. The projections used a CPI equal to 3% per annum.

For the revised baseline projection and the three insurance models, three different scales (Accelerated, Slow and Immediate), which include the impact of inflation, incidence rates and demographic variations were used. (See Table 3.8) The Accelerated scale was employed as a basis for the projections. The other scales were used for sensitivity analysis only. The Accelerated scale was modified when used with Low and High population projection.

- For non-prescribed drugs:

A flat inflation rate equal to CPI + 2% per annum was utilized in order to project drug costs assuming that the inflation rates observed in the last few years would remain the same in the future. This rate was combined

with incidence rates and demographic variations. The projections used a CPI equal to 3% per annum.

Projection Method

For projection purposes, it was assumed that the ratio of persons in each group (AHW, income support, Uninsured, Private) over the entire population of Alberta would remain the same as in year 2004, for each age-band and gender.

2004 costs were projected to 2006 based on a 15% per annum inflation rate (5% for non-prescribed drugs), combined with incidence rates and demographic variations. For prescribed drugs in the baseline projection, 2006 costs were projected to future years using the appropriate increase and incidence rates. For non-prescribed drugs, 2006 costs were projected to future years using the appropriate increase and incidence rates for all models.

Except as specified below, for each age-band/gender cell, the annual drug costs in a particular year are equal to:

- The average cost in year 2004 for this particular age-band/gender cell
- Augmented in order to take account of the cumulative rate of increase since 2004
- Times the incidence rate for this particular year

- Times the number of persons in the age-band/gender cell in this particular year.

For the revised baseline and the three insurance models and for year 2007 onwards, the total annual drug costs per group in a particular year are equal to:

- The total annual drug costs in the previous year
- Augmented by the rate of increase for the particular year, as defined in one of the three different scales (Accelerated, Slow, Immediate).

Calculation of Projected Values

For this paragraph, the following definitions will be used:

- Public fees – It was assumed that administration expenses of public drug programs are equal to 5% of paid claims.
- Private fees – To account for additional expenses inherent to private business, including but not limited to marketing, commissions, cost of capital and profit, a 5% charge on the cost that would be incurred in the public sector was added.
- Ratio 1 = Ratio of paid claims on eligible claims in AHW's non-group drug program – Based on the 2004-2005 fiscal year data, it was assumed that the ratio of paid claims on eligible claims in AHW's non-group drug program would be 81% in 2004, increasing by 0.5% per year until year 2012, and remaining at 85% after that date.

- Ratio 2 = Ratio of paid claims on eligible claims in private drug programs – It was assumed that the ratio of paid claims on eligible claims in private drug programs would be equal to 85%.

In the Baseline projection:

- “AHW” means the government’s share in AHW programs, plus public fees
- “Income support” means the government’s share in income support programs, plus public fees
- “Special programs” means the cost of special drug programs, plus public fees
- “Private” means:

The insured’s share in AHW programs; plus
The insured’s share in income support programs; plus

The drug cost for the uninsured group; plus

The drug cost for the private group times Ratio 2, plus private fees; plus

The drug cost for the private group times (1 – Ratio 2), that is the insured’s share

The non prescribed drug cost.

In the mandatory public drug insurance projection:

- “Public (Current)” means:
The government’s share in AHW programs, plus public fees; plus

The government’s share in income support programs, plus public fees; plus

The cost of special drug programs, plus public fees.

- “Public (Additional)” means:

The drug cost for the uninsured group times Ratio 1, plus public fees; plus

The drug cost for the private group times Ratio 1, plus public fees.

- “Public” means:

Public (current); plus

Public (additional).

- “Out-of-pocket” means:

The insured’s share in AHW programs; plus

The insured’s share in income support programs; plus

The drug cost for the uninsured group times (1 - Ratio 1); plus

The drug cost for the private group times (1 - Ratio 1); plus

The non prescribed drug cost.

In the mandatory public drug insurance with private replacement coverage projection:

- “Public” means:
The government’s share in AHW programs, plus public fees; plus

Continuing Care

Continuing care costs were projected using the Regional Continuing Care Model (RCCM) developed by Alberta Health and Wellness (AHW). The RCCM contains various scenarios related to the transfer of clients from facility-based to supportive living facilities. Scenario #2 was used, which is the basis of AHW analysis.

However some modifications were made to the assumptions used by AHW:

- The population based on projections was used.
- Parameters to account for obsolescence of facilities were added. Based on information provided by AHW, an obsolescence rate of 2.5% was used, indicating that each facility is built for a 40-year lifespan.
- The inflation rate was increased to 4%, in order to be consistent with the assumed income increase rate, since most of the operating and capital expenditure increases are related to income increases.
- Operating expenditures were added to account for the fact that the number of nursing hours provided to long-term care residents should increase from 3.1 to 3.4 hours per day, as recommended in the Report of the Auditor General on Seniors Care and Programs. Based on information provided by AHW, this additional cost will amount to \$70

million in 2006. This amount was projected in future years according to the number of residents in long-term care facilities and to income increases.

Calculation of Projected Values

For this paragraph, the following definitions will be used:

- Public fees – It was assumed that administration expenses of public programs are already included in costs projected by the RCCM.
- Private fees – To account for additional expenses inherent to private business, including but not limited to marketing, commissions, cost of capital and profit, a 5% charge on the cost that would be incurred in the public sector was added. It was also assumed that private insurance companies would allow productivity gains equal to 1% of claim costs from year 2006 to year 2025. No productivity gains were assumed after year 2025.

In the baseline projection, the annual cost is as determined by the RCCM.

In the mandatory public health insurance projection, the annual cost is as determined by the RCCM.

In the mandatory public health insurance with private supplemental coverage projection:

- “Public” is the annual cost is as determined by the RCCM
- “Private” is equal to 10% of public.

In the mandatory private health insurance with public premium pooling projection:

- “Basic coverage” is the annual cost is as determined by the RCCM, plus the difference between private fees and public fees
- “Additional” is equal to 10% of basic coverage.

Non-Emergency Health

Overview

For non-emergency health, the development of projected costs proceeded as follows:

- Annual costs per capita were developed for each age and gender cell.
- Projection factors were computed to apply to the 2005 per capita costs to calculate projected per capita costs in each future year.
- Projected costs for each age and gender cell and in each future year were determined as the product of the relevant per capita cost and the projected population in that cell.
- Total projected costs in each future year were computed as the sum of projected costs over all age and gender cells.

Per Capita Costs

The analysis was based on claims data provided by Alberta Health and Wellness for each of the following broad sub-groups of benefits:

- Emergency room visits with a triage score of three or more.
- Hospitalizations resulting from the emergency room visits referred to above.
- Other hospitalizations, that is, hospitalizations that do not result from emergency room treatment.
- Treatment rendered at hospital ambulatory care centres.
- Treatment provided at a general practitioner’s or a specialist’s office.
- Physician’s services provided at a hospital ambulatory centre following emergency room treatment.
- Physician’s services rendered in connection with in-patient care or in a long-term care facility.
- Physicians’ fees in connection with diagnostic or therapeutic services.
- Community laboratory and other diagnostic fees.

The data was provided separately by benefit and sorted by regional health authority. The data items consisted of the following:

- Age;
- Gender;
- Number of individuals claiming;
- Total number of claims; and
- Total costs.

For each sub-benefit, costs were summed by age and gender cell across all regional health authorities. The total costs by age and gender were summed across all sub-benefits to determine total costs. Per capita costs were computed by dividing these costs by the population in that age and gender cell.

Projection Factors

Projection factors were developed for each benefit subgroup using the method outlined previously in this report. In brief summary, the factors were based on overall Canadian experience, adjusted for inflation and anticipated extra utilization in Alberta.

Projected Costs

The projection factors calculated above were multiplied by per capita costs to calculate projected per capita costs for each age and gender cell. These costs were multiplied by the projected population in each cell to generate total projected costs in each future year.

Federal Transfers

Federal transfers under the Canada Health Act are projected to grow ultimately at CPI plus 3%. This growth rate is lower than the ultimate inflation assumption embodied in the non-emergency health projections, which explains its decreasing significance over the full projection period. Table 2.7 in the Appendix displays the projected values of the transfer, allocated 95% to non-emergency health.

Supplemental Health

The analysis for supplemental health was similar to that for non-emergency health. The main difference was the data source. For supplemental health, data from a representative selection of private sector plans was used as the base since virtually all of the supplemental health benefits are privately insured.

The base analysis produced per capita costs whose effect by sub-benefit was compared to actual 2004 costs obtained from the Canadian Institute for Health Information. Based on this comparison, per capita costs by sub-benefit were adjusted so that totals by sub-benefit were a better fit with the CIHI data. These adjusted per capita costs were projected forward as summarized previously in this report. Projected total costs were calculated for each future year by applying the projected per capita costs by age and gender to the projected population.

**Actuarial
Methodology
Appendix**

This document contains advice, proposals, recommendations, analyses or policy options developed for the Minister of Alberta Health and Wellness, and/or department of Alberta Health and Wellness.

Table 3.8: Scales of increase rates

Year	Medium population			Low population		High population	
	Slow (%)	Accelerated (%)	Immediate (%)	Accelerated (%)		Accelerated (%)	
2006	18.0	18.0	18.0	18.0		18.0	
2007	18.0	18.0	18.0	18.0		18.0	
2008	17.0	16.5	8.0	16.5		16.5	
2009	16.0	15.0	8.0	15.0		15.0	
2010	15.0	13.5	8.0	13.5		13.5	
2011	14.0	12.0	8.0	12.0		12.0	
2012	13.0	10.5	8.0	10.5		10.5	
2013	12.0	9.0	8.0	9.0		9.0	
2014	11.0	8.0	8.0	7.5		8.5	
2015	10.0	8.0	8.0	7.5		8.5	
2016	9.0	8.0	8.0	7.5		8.5	
2017	8.0	8.0	8.0	7.5		8.5	
2018	8.0	8.0	8.0	7.5		8.5	
2019	8.0	8.0	8.0	7.5		8.5	
2020	8.0	8.0	8.0	7.5		8.5
